The first step in correcting heteroskedasticity is to check for an omitted variable that might be causing impure heteroskedasticity. If the specification is as good as possible, then solutions such as the Weighted Least Squares (WLS) or the Heteroskedasticity-Corrected Standard Errors (HCSE) should be considered. The WLS involves dividing the main equation by whatever will make the error term homoskedastic and then rerunning the regression on the transformed variables; a disadvantage of this method is the identification of this proportionality factor. The HCSE is the most popular remedy for heteroskedasticity, and it takes a completely different approach to the problem. It focuses on improving the standard errors of the coefficients without changing the parameter estimates. One of the disadvantages of this technique is that it works best on large samples, and not all computer regression software packages calculate HCSE.

**HICKS, JOHN R.**

1904–1989

Sir John R. Hicks, a British economist and author of twenty books, was knighted in 1964 and received the 1972 Nobel Prize for his contributions to general equilibrium theory and welfare economics. After graduating from Oxford University in 1925, he taught at the London School of Economics (LSE), where he formulated concepts on the elasticity of substitution, relative income shares of labor and capital, and liquidity. At LSE Hicks came under the influence of Lionel Robbins and Friedrich Hayek but broke away from their thinking in his book *The Theory of Wages* (1932), in which he considered unions as monopolies in the sense of rigid wages in a discrimination setting. He joined Cambridge University (1935–1938), where he was swayed by John Maynard Keynes's (1883–1946) writings. Afterward, he was chair of political economy at the University of Manchester. He became a fellow at Nuffield College, Oxford, in 1946 and was the Drummond Professor of Political Economy from 1952 until his retirement in 1965. Hicks continued his work in the areas of fixprice and flexprice markets, liquidity, and inventions.

Hicks's contributions stand out in the areas of applied economics, Keynesian economics, value theory, and technological progress. His method was to modify a theory to fit the facts. Facts are linked to events of the day and have a history that can become dramatic at times. According to Hicks, these dramatic facts are like blinkers waiting to be simplified, theorized about, and selected to explain topical events. Hicks continually revised his theories because economic facts are less permanent and less repeatable than facts in the natural sciences.

Hicks viewed welfare economics as an application of demand theory, focusing on efficient and optimal cost and use of the social product. An efficiency test for welfare benefits tells us how to acquire more of one thing without having less of another thing. Demand theory makes sure that what we are getting more of is not detrimental. A welfare optimum may not be attained in a market with uniform prices, making room for cost-benefit analysis.

Hicks's IS and LL curves represent Keynes's ideas of equilibrium in the goods and money markets, respectively. Alvin Hansen later suggested the label LM for LL (Hansen 1953, p. 144). Darity and Young (1995, pp. 1–14, 26–27) clarified that Hansen's contribution emphasized one sector, while Hicks's contribution emphasized two sectors. Hicks developed a four-equation system representing liquidity preference, $M = L(r, Y)$; investment, $I = I(r, Y)$; savings, $S = S(r, Y)$; and saving-investment equilibrium, $S = I$, where $M$ is money, $I$ is investment, $S$ is savings, $Y$ is income, and $r$ is the rate of interest. The first equation yields the LM curve. If the
interest rate rises, the alternative cost of holding money relative to other assets becomes higher, lowering the demand for money. A rise in income will increase the demand for money. The other three equations yield the IS curve, which shows how income and interest rates adjust to make savings equal to investments. By making unsold inventories depend on the future, the model accommodates short period expectations. In the short term, such as a day, expectations do not change, so the condition for saving to equal investment in the model is achieved. The IS-LM curves can take on special shapes that would prevent automatic adjustments from occurring. Hicks later thought that the IS curve represents a flow concept, and the LM curve, a stock concept. In his Capital and Growth (1965), he proceeded to show that a stock equilibrium over a period would require a flow equilibrium over that period.

Hicks argued against the cardinal view, where utility is added, and for the ordinal view of value, where consumers rank their tastes and preferences. Alfred Marshall and the founders of the marginal revolution examined value with a given utility function. They required a utility surface for consumer maximization. Hicks's value theory examined “what adjustments in the statement of the marginal theory of value are made necessary by Pareto's discovery” (Hicks 1981, p. 7). Vilfredo Pareto postulated a scale of preferences concept, which represented value only by indifference curves. Hicks transformed the cardinal concept of total utility to the marginal rate of substitution between two commodities on an indifference curve. Similarly, he transformed the idea of diminishing marginal utility to diminishing marginal rate of substitution measured by the convex shape of the indifference curve. Following Hicks's work, comparative static analysis that allows prediction from demand analysis can be performed. One of his predictions states that if demand shifts from good 1 to good 2, then the relative price of 2 in terms of 1 would increase, except if 2 is a free good.

On the technology side, Hicks classified inventions as neutral, labor saving, or capital saving. When inventions change the marginal productivity of labor and capital in the same proportion, the invention is called neutral. Hicks predicted that if wages increase, labor's share of output would rise, and that would encourage inventions to replace labor, making them labor saving. In an analogous manner, the same can be argued for capital-saving inventions. In general, when changes in relative prices of factors occur, they induce inventions; otherwise inventions are autonomous. Autonomous inventions are likely to be randomly distributed, while induced inventions are likely to be labor saving.

HIDDEN PERSUADERS

The idea that there are subtle forces within the advertising industry that try to manipulate consumers’ subconscious desires in order to sell products emerged in the first decades of the twentieth century. After World War II, debates about legitimate levels of consumer persuasion in advertising returned with a vengeance. In these years, Western societies’ material wealth and choice of products increased dramatically, which led to ever more advertising being targeted at consumers, especially through the new medium of television. As the Cold War intensified, anxieties spread that governments could use some of the moti-
vational and subliminal persuasion techniques developed by advertisers for political purposes.

These wide-ranging issues were coherently discussed and brought to a wider, non-academic audience by the journalist Vance Packard in his 1957 best-seller The Hidden Persuaders. Packard laid bare how the motivational researcher Ernest Dichter applied psychoanalytic techniques in a way that helped marketers understand and influence consumers' decision-making in the supermarket or automobile showroom. Packard also discussed the subliminal advertising techniques newly developed by the market researcher James Vicary, who in 1957 had designed an experiment in which split-second advertising messages for cola and popcorn were inserted into a movie. The short messages used in Vicary's movie experiment were as invisible to the conscious mind as the psychoanalytic techniques that Dichter developed for his clients, such as the use of subtle sexual imagery to make household products more attractive. Packard argued that motivational research, subliminal advertising, and the method of product placement defied the ideal of open and honest advertising and instead led to forms of “hidden” persuasion that undermined the rational autonomy of consumers and citizens, thus endangering the very basis of liberal democracy.

Similar arguments, though based on a more philosophical analysis of the normative nature of capitalism's political economy, were developed at the same time by the Harvard economist John Kenneth Galbraith. Galbraith's well-known 1958 book on The Affluent Society pointed out that advertising was not merely a means of selling products but, by its very ability to form people's anxieties and desires, a form of social power. In the eyes of Galbraith, traditional economic thought had ignored this fact and had therefore failed to acknowledge that market capitalism was anything but a set of institutions governed by rational decision makers.

Packard's much-discussed ideas reemerged in the 1970s when a new generation of critical journalists and social scientists launched attacks on the hidden persuaders in multinational corporations and governments. Most prominently, Wilson Bryan Key's 1973 book Subliminal Seduction and Stuart Ewen's 1976 publication Captains of Consciousness revived the idea that advertisers willingly applied manipulative and subliminal advertising techniques or images of sexually attractive, youthful, and ever-happy people in order to increase the sale of products. In the 1990s social psychologists approached the issue of consumer persuasion, and of subliminal advertising in particular, with far greater skepticism. While it needs to be acknowledged that advertisers do indeed attempt to influence consumer behavior through all possible means, psychologists have until today found no conclusive evidence that subliminal advertising messages do actually have measurable and reproducible effects on consumers. As a result of this, the discussion of advertising's contested role in capitalist societies has slowly moved away from allegations of hidden psychological seduction or subliminal messages. Rather than looking for evidence of subliminal manipulation of consumers, authors have begun to criticize the often blatant conquest of public spaces and people's private lives by megabrands and the corporate interests behind them. This, in turn, has led to more debates about such things as advertising directed at children, and advertising's relation to potential health risks (associated with products such as cigarettes, alcohol, and fast food). Juliet Schor, for example, has shown how advertising for well-known car, fashion, food, and cosmetic brands determines what many consumers feel they ought to possess and parade in front of neighbors and peer-group members. This type of lifestyle advertising puts pressure on people to spend more time at work—instead of within families or communities—in order to be able to buy more luxury products.

HIERARCHY
A hierarchy is any ranking of objects into grades, orders, or classes of increasing dominance or inclusiveness. As a social phenomenon, hierarchy is a specific type of social organization in which members are divided by status or especially authority. Early use restricted the concept to
sacred rankings of heavenly bodies (e.g., orders of angels) or ecclesiastical and religious rule. Indeed, in his masterpiece *Economy and Society*, the German sociologist Max Weber (1864–1920) first distinguished between political and hierocratic organizations, limiting the latter to those entities with a monopoly of psychic coercion in distributing or denying religious benefits. Contemporary usage refers to any status or authority ranking based on traditional or religious beliefs and customs, formal-legal rules, or persistent inequalities.

Although contested, many scholars believe that humans, like other primates, are hierarchical animals who innately create social rankings within groups. Less contested is that humans throughout history have formed many social hierarchies, ranging from family, tribe, and clan groupings to genders, classes, and castes, to city-states, empires, and nation-states, to bureaucratic organizations including corporations, guilds, unions, political parties, and other civic associations.

Although particular forms differ, all hierarchies are comprised of relationships of superiority-inferiority or domination-subordination. On a daily basis, each individual in a modern society is likely to be a member of several distinct hierarchies with multiple and overlapping jurisdictions. One can simultaneously be a dominant member of a family from a “lower” class and a union leader, subject to the laws of the state in all these roles.

As these examples suggest, hierarchy is ubiquitous in social life. No definitive enumeration of types or forms is possible. At the same time, hierarchy is not universal. Many relationships are carried out between more or less equals, including interactions within peer or friendship networks, transactions in the marketplace, and diplomatic exchanges between great powers in international politics.

Hierarchy is not only varied but dynamic, evolving in form and extent. Although the historical trajectory has not been smooth and unidirectional, hierarchy appears to have deepened in scope and expanded in range over time, and especially in the modern era. With the rise of the nation-state as the encompassing form of hierarchy in the twentieth century, and the deepening of the division of labor within and between societies, greater areas of social life are now more clearly organized by rank and authority than in the past. This trend is challenged in the twenty-first century by globalization, the Internet, and various transnational social networks, all of which carry the potential for alternative, nonhierarchical forms of social organization. Whether these developments signal a long-term change in trajectory or merely a short-term oscillation in the degree of hierarchy remains a subject of debate.

Early understandings of the origins and rules of hierarchy were often functionalist, positing that hierarchies form to solve collective problems within societies. Perhaps best known among these early approaches is Robert Michael’s “iron law of oligarchy,” which posited that the division of labor within organizations combines with the self-interest of organization elites to produce hierarchy even within bodies that pursue egalitarian goals ([1915] 1958). Subsequent scholars have rendered this “law” a contingent tendency, but the forces first identified by Michaels remain important in our understanding of hierarchy.

Contemporary theories of hierarchy can be grouped into three principal schools. Psychological theories ground the ubiquity of social hierarchy in human nature. Associated with the work of James Sidanius and his colleagues, social dominance theory is, perhaps, the most prominent psychological approach today, largely because its multilevel approach avoids many of the problems of strictly individual-level theories. Like authoritarian personality theory and other individual approaches, social dominance theory posits a social dominance orientation that, although universal, varies across the human population and expresses the value people place on hierarchically structured relationships among social groups. Social dominance orientation, in turn, interacts with context-specific institutions and ideologies to produce age, gender, and “arbitrary-set” hierarchies that take the form of clan, ethnic, caste, class or other socially constructed types of discrimination. Although providing a persuasive synthesis of a tendency towards hierarchy in all nonsubsistence societies, social dominance theory lacks a well-developed mechanism for explaining intra- and intersocietal differences in the degree of group-based hierarchy.

The other two main approaches to hierarchy seek to explain precisely the differences in the forms and extent of hierarchy. The contractual perspective dates most clearly from Oliver Williamson’s path-breaking *Markets and Hierarchies* (1975). In a world of costly contracts that fail to specify obligations in all possible future states of the world, Williamson posited, self-seeking actors will tend to form hierarchies when one, but not both, of the parties to a recurring transaction possesses relationally specific assets—or assets that are worth considerably more within that relationship than in their next best use. An example would be a producer of specialized components for a particular brand of automobile. By placing the transactions under unified ownership, and subjecting them to administrative controls (dominance), the incentives of the parties to act opportunistically toward one another are greatly reduced. By internalizing transactions within a hierarchy, actors give up the information and discipline that is otherwise provided by market competition, but reduce the likelihood that they will be exploited by partners. Thus, Williamson and his many followers predict that the producer of specialized components will be subsumed within the automotive firm into a corporate hierarchy. In the
absence of relationally specific assets or frequent exchanges, in contrast, actors will prefer to transact “at arm’s length” in a market. When both parties have relationally specific assets, they hold “mutual hostages” and can coexist effectively in long-term, bilateral, and non-hierarchical relationships. This key insight on hierarchies as solutions to the problem of incomplete contracting in the presence of relationally specific assets has been extended from firms and economic exchange to bureaucracies and other managerial hierarchies, as well as to the analysis of empires, alliances, federal states, international organizations, and a variety of other institutions.

The distributional school lacks a single defining work, but generally understands hierarchies as emerging from initial inequalities between individuals or groups and, then, reinforcing those inequalities to produce an even more highly stratified society. Like the contractual approach, this school conceives of hierarchy as largely negotiated, albeit often under duress and possibly under threat of coercion, between actors who accept a subordinate status in exchange for access to the economic surplus possessed by the would-be superior. In the “big man” societies of Melanesia, for example, individuals acquire status and authority by using their comparative advantage in hunting, gardening, ritual knowledge, or violence to accumulate a material surplus, which they then redistribute to needy villagers. Often pressed to appeal to the big man by unexpected downturns in fortune, the supplicants become followers or subordinates in an informal village hierarchy. Over time, or once embedded into some religious or ideological frame, these relations of inequality become accepted or “normalized” into legitimate rule, with big men or perhaps their sons turning into “chiefs” at some later date. Similar hierarchies unfolded in early monarchies and empires, on the one hand, and in modern capitalist societies, on the other.

A contractual approach understands hierarchy as constructed to prevent possible opportunism, whereas the distributional approach posits that hierarchy emerges from actual inequality and exploitation. Despite this apparent tension, the two schools are actually complementary. Within the distributional approach, subordinates are understood to be locked into hierarchies by the material benefits provided by the superior; although perhaps driven by necessity to appeal to the dominant party for assistance, the subordinates are better off than they would be otherwise, absent that aid. In turn, the benefits of reduced opportunism provide the superior with the economic surplus necessary to assist subordinates while making himself better off as well. This exchange of goods for status and authority, what Herbert Spencer (1820–1903) first called “compulsory cooperation,” provides the glue that holds social hierarchies together. Yet, to understand hierarchy as a bargain of sorts that leaves the parties to an agreement better off than they would otherwise be in an anarchic state of nature—where life would be, as Thomas Hobbes (1588–1679) famously described it, “short, nasty, and brutish”—is not to accept that inequalities of status or resources are fixed and immutable or cannot be made more equal. The history of social struggle is largely one of subordinates claiming a greater and possibly equal share of the social benefits produced by hierarchy. To the extent that hierarchy is an enduring feature of human life, social struggle will persist as well.

HILFERDING, RUDOLF
1877–1941

The economist Rudolf Hilferding was born in Vienna in 1877 to a liberal Jewish family. While studying medicine at the University of Vienna, Hilferding was influenced by his Marxian teacher Carl Grünberg (1861–1940). He abandoned medicine and, together with other Marxists, founded the Marx-Studien journal in 1904. He later moved to Berlin, where he became involved in politics and served twice as Germany’s finance minister (1923, 1928–1929). In 1933 Hilferding fled Germany and settled in Paris, but he was later arrested and was murdered by the Gestapo in 1941.

Hilferding became noted for his criticism of the Austrian economist Eugen von Böhm-Bawerk (1851–1914) with the publication in 1904 of his book Böhm-Bawerk’s Criticism of Marx. For Böhm-Bawerk, the market determines prices, and competition requires the freedom of capital and labor to yield equal profit rates. For Hilferding, in contrast, the market is conditioned by the relationship of surplus value to wages and its distribution among productive agents, while competition is a reciprocal relationship between products (Sweezy [1949] 1966, p. 191). For Böhm-Bawerk, labor is a disutility of work; for Hilferding, “labor is the social bond uniting an atomized society” (Sweezy [1949] 1966, p. 134).

Hilferding used Marxian schemata to criticize Böhm-Bawerk. He found different prices for each sector but the same total price and value for all sectors. To Hilferding, Böhm-Bawerk’s position equates price as equal to value. Hilferding underscored that Marx had modified value in a definite way, where the law of value passes to the law of motion through commodities. In the labor theory of value, commodities are exchanged for their values. This is not a condition of exchange in general. Changing historical conditions modify exchanged value, and “all that is necessary is that we should understand the course of prices to be a modification of the pre-existing course of prices. … Böhm-Bawerk’s mistake is that he confuses value with price” (Sweezy [1949] 1966, p. 156).

In Finance Capital (1910) Hilferding built on Marx’s work in the areas of joint stock companies and cartels, crises, and imperialism. Hilferding argued that as capitalist industries develop, they form cartels to avoid competition. At the same time a concentration of banking evolves as banks come to encompass huge financial capacity. Thus, as the banks’ capital is invested in industry, it becomes finance capital.

The high profits of cartels find their way into banks. Banks seek to export capital as investment opportunities decline at home and form general cartels. To foster exports, tariffs and protectionism are encouraged. As cartels and banks expand, finance capital becomes increasingly concentrated, creating a Marxian money-to-money circuit, $M - \ M'$. Hilferding’s unique contribution is that shareholders no longer rely on profits. They can be money capitalists relying on interest. He referred to this gain as promoter’s profits, $P = \frac{100Y}{d} - \frac{100Y}{p}$, where $d$ is dividend, $p$ is average profit, and $Y$ is the yield of the enterprise. The formula shows a positive yield when a corporation transfers productive profit-yielding capital into interest-yielding capital (Hilferding [1910] 1981, pp. 114, 117).

Hilferding presented a crisis theory that is based primarily on proportionality between the capital-goods and the consumption-goods sectors. When a commodity plays the dual role of money ($M$) and commodity ($C$), a crisis is possible in the $C_1 - M - C_2$ circuit when money is hoarded. For Hilferding, “a crisis is simply the point at which the rate of profit begins to fall” (Hilferding [1910] 1981, p. 257). Marxian crises result from falling profits and underconsumption. Hilferding emphasized the disproportion in which commodities are produced and deemphasized the underconsumption theory. As the aggregate product is represented by the sum of constant capital, variable capital, and surplus value, the part of constant capital that is used up must be replaced, and if variable capital and surplus are consumed, proportionality is maintained, and production will be sustained.

Hilferding’s finance capital is marked by the highest level of concentration of economic and political power. This is due to mergers of corporations, which eliminate trade, create substantial profits that strengthen a firm against downswings, and allow financial capital controlled by banks to enter industries. At this stage capitalism has withered but is not dead, and economic power is transformed into state control. State power breeds international conflicts, while internal conflicts increase with the concentration of capital. The proletariat’s response to this imperialism is a demand for socialism. A country can maintain its capital only by increasing military operations. V. I. Lenin (1870–1924) considered this “a very valuable theoretical analysis” (Lenin [1917] 1973, p. 11). While in Lenin’s version competition and monopoly are maintained, in Hilferding’s version organized capitalism without competition and capitalist control ensues as in the socialist planned economy.

The American economist Paul Sweezy (1910–2004), a major critic of Hilferding (Sweezy [1942] 1970, p. 268), maintained that finance capital is a temporary phase, as many corporations obtain financing from their internal sources of funds, and that banks now have a less powerful role. In addition to pointing out that imperialism is not a necessary state of capitalism, the Austrian economist...
Hinduism

Hinduism embraces a great diversity of beliefs and forms of worship, and it has therefore been called a “family of religions” rather than one religion. Hindus form the majority population of India (approximately 82% of India’s 1.25 billion people). About 45 million Hindus live outside of India, mostly in the neighboring countries of Nepal (where Hinduism is the state religion), Bangladesh, and Sri Lanka. About 2.5 million Hindus live in North America, where they have established dozens of temples.

British authors in the early nineteenth century coined the term “Hinduism” by adding “-ism” to the word Hindu, which had been used by the Ancient Persians to identify the inhabitants of the land beyond the Indus River. Hindus themselves had called their tradition the term “Hinduism” by adding “-ism” to the word Hindu. There were two terms for it: "Aryan Dharma" and "Nara-Dharma." When the settlements had to be abandoned around 2000 BCE, due to a major climatic change, most moved east into the Yamunā-Ganges Doab, which became the new home of Vedic civilization, with Mathurā (on the Yamunā) and Vārāṇasī (on the Ganges) as main cultural centers.

Joseph Schumpeter (1883–1950) considered Hilferding’s monetary theory to be old-fashioned (Schumpeter 1954, p. 881).

Hinduism is closely tied to the land, and the Mātrī-bhūmi (Motherland) has a unique emotional appeal for Hindus. The physical features of the country are associated with Hindu gods and goddesses and with Hindu religious practices and eschatological expectations. The great rivers of India are not only important bodies of water; they are also sources of inspiration and ritual purification, as well as divinities to be worshipped. Many towns and cities along their banks are places where pilgrims congregate to obtain supernatural blessings. In addition, mountains such as the Himalayas, the Vindhya, the Ghats, and the Nilgiri Hills are the abodes of gods. Hundreds of thousands of temples, small and large, embellish India’s landscape, visibly transforming the country into the Hindu Holy Land.

SCRIPTURES AND RITUALS

Hindu scriptures have come down through the ages in two major streams: the Vedas and the Agamas. The Vedas are the literature of the religious professionals, to be memorized and recited only by Brahmans. They comprise the four Samhitās (collections of hymns) and a large number of Brāhmaṇas (ritual texts), Āranyakas (forest treatises), and Upaniṣads (mystical writings). The Agamas are the sacred literature of the people at large. The Great Epics, the Rāmāyana and the Mahābhārata, are also important sources of Hindu religion.

Many Hindus consider the Bhagavadgītā, a section of the Mahābhārata, an epiphenome of their religion. The Purāṇas, bible-like compendia of Hindu lore, are widely read by Hindus from all classes. Numerous texts are considered to be revealed scriptures by the followers of specific worship traditions. They contain creation narratives, moral teachings, worship rituals, genealogies of kings and patriarchs, myths of gods and goddesses, edifying stories, and eschatological lore. Based on these texts, poets and playwrights such as Kālidāsa and Bāṇa (fifth or sixth century CE) produced dramatic literature of a high order in Sanskrit. Poet-saints such as Tulsīdāsa and Kamban (sixteenth century CE) created popular vernacular versions of the classics that continue to be performed, while countless “Bollywood” films take their stories from these books.

The language of the most ancient literary documents of Hinduism, “Vedic” is an archaic form of Sanskrit, the “refined language,” standardized around 600 BCE by Pāṇini. Sanskrit was called Devasvan, or the “language of the gods.” It became the language of Hindu scholarship and classical poetry as well as Hindu religious literature. All modern North Indian vernaculars are largely derived from Sanskrit.

Domestic and public rituals were a prominent feature of early Vedic culture and were considered indispensable for the well-being of individuals and society. In their performance, hundreds of intricate and interrelated rules had...
Hinduism

to be observed. The construction of the altars demanded the solution of difficult arithmetic and geometric problems, and the timing of sacrifices was based on precise astronomical observations. The change of seasons was accompanied by rituals, as were the various life stages. Public offerings ensured the fertility of fields and domestic animals, while home rituals accompanied birth, adolescence, marriage, and death. In later centuries puja, the worship of great gods like Viṣṇu and Śiva, became the predominant form of religion. But the performance of Vedic rituals continues to this very day. For example, Brahmans still recite Vedic hymns at upanayana (initiation), vivāha (marriage), and anuyēṣṭi (last rites). Many Hindus participate in daily temple worship and partake of consecrated food (prasāda), and the major temple festivals are great public events for every village and town. Domestic rituals, such as offering food to the deity or waving lights before the image of the deity, are also still widespread in India.

SOCIAL ORGANIZATION

Traditional Hindu society functioned on the assumption that humans are not born equal and that their birth in different varnas (classes) defines their specific rights and duties. According to the Puruṣa Sūkta, the Vedic creation myth, Brahmans, born from the Great Being’s mouth, were the custodians of the Veda, the highest in rank. Kṣatriyas (or Kshatriyas), born from its chest, were rulers and warriors. Vaiśyas (Vaisyas), born from its belly—businesspeople, artisans, farmers and clerks—had to provide the necessities of life for society at large. Śūdras (Sudras), originating from its feet, were to serve the upper three varnas. The three higher varnas alone were entitled to receive the samskāras (sacraments) that made them devī-jātis (twice-born). Ātri Śūdras (Ati-sudras), the people below the Śūdras (also called Aspṛīyas or untouchables) were outside the pale of Hindu society proper. They were relegated to doing work that was considered ritually polluting, such as skinning carcasses, cleaning latrines, and disposing of the dead. They were not allowed to dwell in the village proper and were not entitled to using amenities reserved for caste people. Each of the four varnas consists of hundreds of jātis (birth lines, or subcastes) that also observe ranking among themselves.

Duties also varied with respect to stages in life. A twice-born male was to spend the first twelve years after initiation with a reputable teacher (brahmacarya). He then had to marry and to procreate children. After the children had grown up he was to live as a forest-dweller in a life of simplicity and meditation. Finally he was to enter the stage of renunciation, and as a homeless pilgrim he was to visit holy places until death relieved him of the burden of his body. While this schema was never literally carried out on a large scale, it provided a value orientation that was widely respected.

Early in their history, Hindus developed principles of theory and practice of government (rajā-dharma). The Mahābhārata devotes long sections to this, and the Kautilya Arthāśāstra, ascribed to the prime minister of Chandragupta Maurya (321–293 BCE), provides a detailed description of a well-ordered professional administration. One of the aims of the Hindu jāgāran (awakening) that began in the early twentieth century was to reestablish India as a Hindu nation. The Hindū Mahāsabhā, the first modern Hindu political party, was founded in 1909. It maintained that “Hindus have a right to live in peace as Hindus, to legislate, to rule themselves in accordance with Hindu genius and ideals and establish by all lawful and legal means a Hindu State, based on Hindu culture and tradition, so that Hindu ideology and way of life would have a homeland of its own” (Pattabhiram, p. 217). Vir Savarkar, one of its main ideologues, strove to unify Hindu-India under the banner of “Hindutva,” a cultural Hindu identity. In 1926, K. V. Hedgewar founded the Rāṣṭriya Swayamsevak Sangh (RSS) in order to counteract Muslim influence in Indian politics. The RSS leader M. S. Golwalkar was instrumental in creating the Vītāvā Hindū Parisrād in 1964, which aims at unifying all Hindus across the different denominations. It vigorously promotes and defends Hindu interests both within India and abroad.

ANCIENT CHALLENGES

In the sixth century BCE, movements arose in India that challenged the necessity of rituals (especially the animal sacrifices) and the mediating function of Brahmans. Among the breakaway factions that survived the centuries are Jainism and Buddhism. Jina Mahāvīra, the last reformer of a more ancient religion, declared ahimsa (nonkilling) to be the highest moral principle. Gautama Buddha, the latest of a long series of “Enlightened” ones, taught that ethical perfection, rather than birth, made a person a Brahmin. For several centuries the traditions based on the teachings of these sages, Jainism and Buddhism, respectively, were the majority religions in India. Under the Imperial Guptas (320–540 CE), the Brahmans launched a major campaign to lure people back to Hindu rituals. They built temples and encouraged the composition of popular religious books. After the disintegration of the Gupta Empire, many smaller kingdoms arose in various parts of India. Hindu culture also reached out to Southeast Asia as far as the Philippines, and the languages and arts of Southeast Asia still show a strong Indian influence. From the twelfth century onward, most of India came under the rule of Muslim invaders, who destroyed many Hindu temples and built mosques on
their sites. These actions are still the cause of much friction between Hindus and Muslims today.

THE TRANSMISSION OF HINDUISM
Vedic religion was family based. Specific branches (śakhas) of the Veda were preserved in individual families, who held hereditary offices in public rituals. The home was also a center for religious practices, and the sacred hearth-fire was not allowed to die out. Families were responsible for the life-cycle rituals, and husband and wife together had to perform the domestic rituals. Young boys moved into the families of gurus to be taught. The role of the guru reached great prominence when specific worship communities developed under the leadership of charismatic personalities, who often claimed to be the embodiment of a deity. These ācāryas (Masters) shaped mainstream Hinduism and still exercise great influence on Hindus at large, regulating the lives of their followers and reinterpreting scriptures and traditional teachings.

Pluralism was a hallmark of Hindu religion from its very beginning. Many gods and goddesses are invoked in Vedic hymns, and Hindus continue to worship a great variety of deities in their temples. There is no common creed to which all Hindus subscribe, nor is there a single doctrine or practice that is followed by all Hindus, except perhaps the nominal acceptance of the Veda as a revealed scripture and the belief in karma and rebirth. It is natural for Hindus with an inquiring mind to analyze and investigate the teachings of their traditions, and professional philosophers with a Hindu background also deal with religious issues in a philosophically meaningful way. Hindu philosophical systems (darśanas) are not mere abstract constructs, they are also paths for the realization of the highest purpose of life (sādhanas). Among the qualifications required for beginning philosophical study is the earnest desire to find liberation from the sufferings of the cycle of rebirths (samsāras), caused by ignorance concerning the true nature of reality.

Education was always a high priority for Hindus: the early life of Brahmins was devoted to study, and continued private study (śvādhayāsa) was one of their lifelong obligations. In addition to the private, tutorial-like teaching from guru to disciple, imparted in the guru’s home, schools were attached to ashrams and temples from early on. The well-organized, ancient Indian universities, which were publicly as well as privately sponsored, taught not only the Veda, but also the “eighteen sciences,” later supplemented by the “sixty-four arts.” The basic curriculum included linguistics, arts and crafts, medicine, logic and spirituality. High ethical standards were expected both from students and teachers. The most famous of these universities were Takṣaśilā in the Punjab, and Nālandā and Mithilā in Bihar.

Hindus believe in a balance of values, expressed in the four aims of life (purusārthas): the acquisition of wealth (artha), the enjoyment of life (kāma), the practice of morality (dharma), and the search for final emancipation (mokṣa).

HINDU SCIENCE
The central ritual of Vedic culture was performed at astronomically fixed times on altars built with specifically produced bricks arranged in a prescribed geometric pattern. The altar was conceived as a symbol of the human body as well as of the universe: the 360 bricks of an altar represented the 360 days of the year and the 360 bones in the human body. The building of altars in different configurations, and their change in shape and volume, involved a sophisticated geometry. The Śūdra-sūtras provided the rules for constructing a variety of shapes of altars and their permutations. Astronomical knowledge of a fairly high order was required to determine the right time for the performance of Vedic sacrifices. One of the auxiliary Vedic sciences, the Jyotiṣa, explains how to determine the positions of the sun and moon at solstices, and of the new and full moon in the circle of the twenty-seven nakṣatras. Geometry and other fields of Indian mathematics developed out of the requirements for the Vedic sacrifice. Algebra, in spite of its Arabic name, is an Indian invention, as are the concept of “zero,” the decimal system, and “Arabic” numerals.

The Atharvaveda contains invocations relating to bodily and mental diseases. Its auxiliary Ayurveda, (life science) was mainly oriented toward preventing diseases and healing through herbal remedies. Good health was not only considered generally desirable, it was viewed as a precondition for reaching spiritual fulfillment. Medicine as a “charity” was widely recommended and supported by Hindu rulers. Two Indian medical handbooks, the Cāraka-sāṃhitā and the Suśruta-sāṃhitā, were the result of centuries of development and became famous in the ancient world far beyond India. Ayurveda was also applied to animals and plants, and there is an ancient handbook for professional gardeners and a text for cattle veterinarians. Other works deal with veterinary medicine relating to horses and elephants. Ancient India had both hospitals and animal clinics, and Gośālas, places in which elderly cattle are provided for, are still popular in some parts of India. Ayurveda was the source of much of ancient Greek and Roman, as well as mediaeval Arabic medical knowledge. In modern times, Ayurvedic pharmacology has become recognized by major Western pharmaceutical companies and researchers.

In connection with the building of temples, Hindus developed a great architectural tradition. No village or city was deemed inhabitable without a temple. Professional
handbooks like the *Manasāra* and the *Mayamata* provide artistic and religious canons for the architects and sculptors.

_Adhyātma-vidyā_, the science relating to *Brahman*, the Supreme Reality, was considered the highest branch of science. It rested on personal experience, a coherent epistemology, and the exegesis of revealed utterances. The ideas of the Upanishads were further developed into the systematic of Vedānta philosophy, mainly laid down in numerous commentaries on the *Brahma-sūtras* ascribed to Bādarāyaṇa (second century BCE). Beginning with Śaṅkara (eighth century CE), through Rāmānuja (eleventh century) to Madhva (thirteenth century), the greatest minds of India have endeavored to cultivate the science of the eternal spirit.

**WHO IS A HINDU?**

For many centuries, membership in the Hindu community was restricted to those who were born from Hindu parents and who had undergone the various prescribed rituals that made a Hindu a full member of the Hindu community. But even in ancient times, many foreigners who came to India adopted Hindu thought and culture. With the establishment of British rule in India and the advent of Christian missionaries, the interest of Hindus in spreading their religion abroad was awakened. Swami Vivekananda’s much celebrated presentations at the World Parliament of Religions in Chicago in 1893, and his subsequent journey through the United States and England, resulted in the establishment of Vedanta Centers. Mahatma Gandhi, who led the Indian independence movement to success on the basis of the Hindu ideal of nonviolence, did much to gain worldwide respect for Hinduism. Sarvepalli Radhakrishnan, the president of India from 1962 to 1967, became the voice of the twentieth-century Hindu intelligentsia, representing Hinduism as the most advanced form of universal spirituality. The numerous Hindu swamis and gurus who came to the West beginning in the 1960s familiarized thousands with sectarian Hinduism and attracted many Westerners to joining Hindu religious communities. In the twenty-first century, many Hindu authorities have given up their reservations and freely accept Western converts to Hinduism.

### HIP HOP

Hip hop is a bundle of cultural practices that coalesced during the 1970s. It was largely developed by black and Latino youth in the Bronx, a New York City borough particularly affected by urban blight, middle-class flight, and deindustrialization. *Hip hop* is often used interchangeably with the term *rap* to describe the musical dimension of the cultural movement. *Hip hop*, though, is an umbrella term that refers to four distinct cultural forms. *Graffiti* (or *bombing*) is an art form that was typically staged on New York City subway trains before it gained mainstream recognition in the early 1980s. The second cultural practice associated with the emergence of hip hop is *breaking* or *breaking* (as performed, for example, by the Rock Steady Crew). Breaking has obvious roots in earlier forms of dance within the United States and provided the inspiration for the term *b-boy*, a male break dancer. The remaining two elements—*deejaying* and *emceeing*—constitute the primary distinguishing characteristics of the musical idiom associated with hip hop culture. The first refers to the role of turntables in the making and mixing of rap music rhythms in the place of live musicians (in the traditional sense). The emergence of the emcee as a dominant figure reflects the role the spoken word plays in hip hop, distinguishing it from the genres of gospel, blues, and rhythm and blues, in which singing features prominently. With time, graffiti and break-dancing became less prominent and commodifiable, as the deejay and especially the emcee emerged as the genre’s iconic representatives.

The three individuals most associated with the music’s early development were Bronx residents Kool Herc, Afrika Bambaataa, and Grandmaster Flash. Herc is celebrated for his adaptation of the sound-system culture—bass and volume—of his native Jamaica to the parks and community centers of the Bronx. Afrika Bambaataa, the child of Caribbean immigrants, would contribute his eclectic taste and his willingness to use rock, reggae, soul, and jazz musical sources to create rap
music. Grandmaster Flash, an immigrant from the Caribbean island of Barbados, is known as the pioneer in the realm of turntablism and for developing the art of mixing. At this early stage, the primary figures associated with the genre were all deejays. Their work, in the aggregate, provides evidence of the influence of Jamaican popular culture upon rap’s emergence (for example, producers such as Lee Perry and King Tubby, and performers such as I-Roy and U-Roy).

Hip hop emerged as a prominent form of black popular culture outside of the New York area with the success of the Sugarhill Gang’s “Rapper’s Delight” (1979), which was released on an independent label owned by musician and producer Sylvia Robinson. Indeed, most of the music’s pioneers did not consider rap to be commercially viable and, as a consequence, did not try to make and distribute recordings. The developing interest in these practices by the culture industries created new stars, such as Kurtis Blow, the Funky Four Plus One, and the Treacherous Three, along with older groups such as Grandmaster Flash and the Furious Five, Afrika Bambaataa and the Soul Sonic Force, and the Cold Crush Brothers. The genre also achieved crossover popularity through the work of pop groups such as Blondie (“Rapture,” 1980). Up until this juncture, most observers saw rap as a novelty and most of the records were made for independent labels.

As a recorded medium, the first classic era of rap music was launched with the release in 1982 of Afrika Bambaataa and the Soul Sonic Force’s “Planet Rock” and Grandmaster Flash and the Furious Five’s “The Message.” The former recording revealed a strong influence by the German electronic group Kraftwerk. The latter, with its relatively pointed social message, was recorded and released against the will and without the participation of most of the group’s members (including Grandmaster Flash), and would signal the changing balance between deejays and emcees, with the turntablists gradually fading in prominence. Following in the wake of these canonical recordings was the work of New York–area artists such as Run DMC, LL Cool J, Boogie Down Productions, Eric B. & Rakim, and Public Enemy. As the music’s influence spread beyond the inner city, suburban youth became involved as artists, including most prominently De La Soul and the Native Tongues movement. Hip hop’s audience crossed boundaries with time, and it is suggested that at points as many as three-quarters of the consumers of the music were neither black nor Latino.

The effects of crack cocaine and its associated industries energized (and in some instances subsidized) new forms of rap music. The kinds of rap that emerged from the west coast of the United States (especially Los Angeles and Oakland) were distinguished from their counterparts in the Northeast not only by their linguistic innovations and source preferences (e.g., Parliament/Funkadelic and Zapp versus soul jazz and James Brown), but also, at least initially, by their moral economies. By the middle of the 1990s, these perspectives provided the dominant template for the making of rap music in the South (OutKast, Petey Pablo, and others, in the wake of Miami’s 2 Live Crew), the West (N.W.A., Ice T, Ice Cube, Dr. Dre, Snoop Doggy Dogg, and Tupac), and the Northeast (the Notorious B.I.G., Jay-Z, and later 50 Cent).

The musical genre of rap has proved to be diverse in many respects. Nevertheless, throughout its history it has been a space that has privileged masculine perspectives and—in contrast to rhythm and blues, which is often cast as its feminized other—has featured few successful women practitioners (exceptions include Roxanne Shanté, MC Lyte, Queen Latifah, Lauryn Hill, Lil Kim, and Foxy Brown). Indeed, the genre as manifested in its lyrics, its publications, and in film became relatively misogynistic. Its boundaries would also—in contrast to other black music forms, such as house music—discourage the open participation of lesbians and gays with its often ritualistic deployment of homophobic discourse. Its successful practitioners have also been overwhelmingly black with few exceptions (e.g., Eminem). Hip hop music and culture have also had a great impact abroad throughout Europe, Africa, parts of Asia, and the Americas, and have generated new genres in response, including drum and bass, reggaeton, grime, and kwaito.

Hip hop defined the generation coming of age in the 1980s and afterward. Moreover, with its particular sartorial, linguistic, gender, and class inflections, it represents in the eyes of many a rejection of the aesthetics, values, and goals of the civil rights generation. It has also been used to market clothing, running shoes, and subsequently a wide range of consumer goods, as well as politics (most prominently in the form of the Hip Hop Action Network and the Vote or Die voter registration campaigns mounted during the 2004 American national elections).

HISTORY, SOCIAL

Social history emerged as a discipline over the course of about twenty years at the conjunction of two seemingly contradictory schools of historical writing: English social history and the French Annales school.

Defined by George Macaulay Trevelyan (1876–1962) as “history with the politics left out,” English social history sought to examine the “manners, morals and customs” of the English people within a disciplinary rubric that placed social history alongside political, economic, and, in some quarters, labor history as discrete subfields (Trevelyan 1942).

The Annales school, founded in 1929 by Marc Bloch (1886–1944) and Lucien Febvre (1878–1956) and named after the journal Annales d’histoire économique and social, sought quite the opposite. Bloch and Febvre intended a new “science of society” that would incorporate all domains of the human and social sciences. The two envisioned their project in diametric opposition both to Durkheimian sociology, which they felt merely rummaged history for support of its theories, as well as historical renderings that purported to render through a catalogue of facts an objective past. They and their colleagues sought at once to investigate the differentia of past presents and to come through these investigations to a fuller sense not only of how a given society came together in all its interrelated elements, but also human society as conceived as an entity in which all historical moments participate and elucidate. What was envisioned was a massive inductive project incorporating myriad local histories that would yield at an endlessly forestalled future time, a “history of society.”

The first Annales school was enthusiastically received by what was known as the Communist Party Historian’s Group in Britain (1946–1956). Though putatively an organ of the Communist Party, under the de facto leadership of the British journalist Dona Torr (1883–1957), the group enjoyed a free and open discussion. Its members included E. P. Thompson (1924–1993), Dorothy Thompson (1894–1961), Christopher Hill (1912–2003), Rodney Hilton (1916–2002), Eric Hobsbawm (b. 1917), and George Rudé (1910–1993), among other future notables of social history. The group’s concerns maintained a tension between two poles that would inform the members’ later work: at one end an interest in social transformation, specifically the transition from feudalism to capitalism, and at the other, an interest in the “manners, morals and customs” of the poor in relation to those transformations. The first roughly corresponded to discussion of Maurice Dobb’s (1900–1976) Studies in the Development of Capitalism (1946) and the second to A. L. Morton’s (1903–1987) People’s History of England (1938).

In 1952, the group founded the journal Past and Present, which sought to give voice to these concerns and to engage with non-Marxist historians interested in similar lines of inquiry. In the first issue, Hobsbawm published his groundbreaking analysis of the machine breakers, which demonstrated that Luddite riots were not resistance to the machine as such, as has long been argued, but to the “machine in the hands of the capitalist” (Hobsbawm 1952). He argued that in the absence of organizational and political avenues, such protests should be read as “collective bargaining by riot.” The theme was later expanded in a series of similarly pathbreaking studies by Rudé on the crowd. Meanwhile, Hill demonstrated that the “manners, morals and customs” of the poor were themselves a source of political struggle in his important essay “Puritans and the Poor,” which examined the disciplinary techniques of the nascent English bourgeoisie (Hill 1952).

The group’s twin concerns were on full display in E. P. Thompson’s magisterial work The Making of the English Working Class ([1963] 1968), which brought to bear his understanding of culture as a “whole way of conflict.” Thompson argued that class comes into being as a result of struggle; through this struggle, persons become conscious of their interests and themselves as a class over time. Thompson therefore rejected sociological definitions that sought to define class as distinct from historical struggle and, by extension, context. What resulted was a
notion of class that Mikhail Bakhtin would call “novelistic,” in that class designated an open-ended, dialogic “unity” which, through the ceaseless interpenetration of other voices and experiences, undoes and redees its own provisional unity. From a methodological standpoint, Thompson’s work was highly innovative, incorporating literature (from high to very low), folklore, local archives, and spy reports in a way that elucidated the complex moral and symbolic universe in which class struggle was imbricated. In *The Making of the English Working Class* and in later works dealing with grain riots, game laws, and time and its relation to work discipline, Thompson demonstrated a subtle understanding of human agency that did not recognize, for example, time or the law as necessarily instruments of ruling-class power (which they were initially, he allowed). Instead, he suggested that these created circumstances through their own claims to universality that permitted a defense (if only a weak one at first) on those very same grounds against the arbitrary actions of elites. Thompson presented his objects of study as situated in historical processes, the relative meanings of which were constituted through struggle and human agency.

Thompson inaugurated a new version of social history in the late 1960s and into the 1970s with mixed success. On the one hand, authors such as Eugene Genovese (b. 1930) and Herbert Gutman (1928–1985) produced subtle and far-reaching studies in the American context that recovered local knowledges and successfully mapped larger processes through them. On the other, there was a tendency to shrink back from the theoretical engagements of these authors, producing something closer to Trevelyan’s “history with the politics left out” even in studies of working-class culture. It was against this trend that Hobsbawm wrote his important essay “From Social History to the History of Society,” which appears in his collection *On History* (1997), urging a reconnection of such studies to larger historical processes.

While culturalist “advocacy” readings of the working class turned away from larger issues, the rise of historical sociology—with its use of demography, cliometrics, and other statistical tools inspired by the second and third waves of the Annales school—tended to efface culture and, with it, class conflict entirely. The twin recoil from the interventions of the Communist Party Historian’s Group inspired important and often scathing critiques by Tony Judt, Elizabeth Fox-Genovese and Eugene Genovese, and Geoff Eley and Keith Nield.

CRÍSES

In the late 1970s and early 1980s, the field of social history found itself in another sort of crisis entirely. Feminists began calling into question the primacy of class in historical analysis, arguing that gender complicated and problematized easy assumptions regarding the universality of the class experience, which they argued tended to be gendered male. While the worst of these arguments reproduced the atheoretical “advocacy” histories discussed above in the context of gender, the best of these critically engaged the concept of class and have significantly enriched contemporary understandings of past societies. The scholars Deborah Valenze and Barbara Taylor revisited Methodism (a religion founded by John Wesley in the eighteenth century) and Owenism (a theory developed by utopian socialist Robert Owen, often considered a precursor to Marxism) respectively, demonstrating the egalitarian promises and realities of each for women that E. P. Thompson had overlooked. Similarly, Christine Stansell examined gender and working-class formation in New York City in her delightful *City of Women* (1987). Judith Walkowitz produced an influential social history of Victorian prostitution on which Stansell drew, and she later expanded on these themes, drawing successfully on the work of Gareth Stedman Jones (b. 1942) and the literary scholar Coral Lansbury’s (1933–1991) work to elucidate the physical and cultural landscape around the Jack the Ripper murders. The historians Sonya Rose and Anna Clark have sought more frontally to rehabilitate the concept of class while addressing what the latter views as its misogynist articulations and realities. Catherine Hall, first with Lenore Davidoff in *Family Fortunes: Men and Women of the English Middle Class, 1780–1850* (1987), engaged the deep intersections of class and gender in the formation of the English middle class, and later alone demonstrated the ways these were both deeply implicated in colonialism. Most suggestively, the literary scholar Mary Poovey has, like Hall, opened exciting avenues for examining the manner in which class, gender, and race influenced each other, inflecting every aspect of social life in the nineteenth century.

Coeval with the rise of feminist studies in social history arose what has come to be called the linguistic turn, which can be traced to Stedman Jones’s 1982 essay “The Language of Chartistism” (Chartism being a movement for the franchise on the part of the middle and working class, beginning formally in the late 1820s and continuing through the Reform Act of 1867). Stedman Jones argued that an examination of Chartist language revealed a fundamentally political movement that obscured rather than articulated working-class interests. The historians Patrick Joyce and James Vernon pushed Stedman Jones’s observations still further, the former arguing that class should be replaced by what he feels to be a more fluid and soft term, the *people*. Drawing on the French sociologist Jean Baudrillard’s (b. 1929) conception of the *mass*, Joyce has argued for a formless corpus whose solidarities are formed and mobilized through political speech, only to form anew in different configurations in different contexts.
Criticisms of Stedman Jones, Joyce, and Vernon have been many and often unhelpful, a situation exacerbated by the posturings of the latter two. Joan Scott has offered a successful critique of Stedman Jones, arguing that his somewhat literal reading of political discourse excises the gendered nature of that language (Scott 1988). Eley and Nield have argued that Joyce's formulations rely upon a straw man of a crudely economic, reductionist Marxism jettisoned from social history nearly from its inception. Joyce and Vernon's most sympathetic and formidable critic, James Epstein, has argued that their formulations fail to take into account the conditions of the production and dissemination of political speech, especially the crowds to whom that speech is addressed.

In some renderings, social history has been in crisis since it began. When it has been successful, it has embraced new ideas and domains of inquiry by holding these in creative tension with the analytical purchase of its past discoveries. It is only through these engagements variously with feminism, postcolonial studies, Marxism, anthropology, and, more recently, literary studies that it has achieved something like its foundational concern of a "history of society" articulated by Bloch and Feibvre and reiterated variously by Hobsbawm and, later, Eley and Nield.

Hite, Shere

1942–

Author Shere Hite ignited nationwide discussion on the roles of gender and culture in sexuality with the publication of her controversial series of books known as the Hite Reports. Hite has been praised by some for advancing theories of human sexuality by incorporating concepts of societal influences on sex and by revealing the previously overlooked sexual experiences of women. However, she has been criticized by many social scientists for her research methods, which have been described as nonscientific and biased.

Hite was born Shirley Diana Gregory in Saint Joseph, Missouri, and was later adopted by her stepfather, Raymond Hite. She earned a bachelor's and a master's degree in history at the University of Florida and subsequently enrolled in a doctoral program at Columbia University from which she ultimately withdrew. The first book in Hite's series, *The Hite Report: A Nationwide Study of Female Sexuality*, was based on replies to a questionnaire distributed by Hite while she served as director of the Feminist Sexuality Project for the National Organization for Women (NOW). This book, consisting primarily of verbatim responses from more than three thousand women, became a best seller when it was published in 1976. Contrary to the theories about female sexuality prevalent at that time, which were centered on vaginal penetration, the testimonies of women quoted in Hite's book demonstrated that almost all women could regularly achieve orgasm through clitoral stimulation. In contrast, only about 30 percent of women sampled reported achieving orgasm regularly through vaginal intercourse. Feminists embraced the book for presenting attitudes and experiences in the women's own words and for reporting findings that suggested that a woman's sexual enjoyment was not dependent on the presence of a male. Ultimately, the first Hite Report called for an expansion of the conceptualization of female sexuality to include desires, emotions, and cultural influences on expectations of sex, rather than the limited focus on biology and reproduction.

The inclusion of emotions and societal influences in sexuality theory was also prevalent in Hite's second publication, *The Hite Report on Male Sexuality* (1981). This work argued that male sexuality extended beyond the accepted model that men are solely interested in penetrative sex. Rather, men desire a diversity of sexual activities and are affected by cultural expectations regarding emotions and behavior. Hite has gone on to publish more than ten books generally focusing on sexuality and relationships.

Despite the commercial success of Hite's publications, her methods drew criticism from the scientific community. Although the sample for Hite's initial study of over three thousand women is seemingly large, it represents only 3 percent of the 100,000 women who were sent Hite's questionnaire. Such small response rates are generally indicative of a self-selecting bias, in that only the women who felt strongly enough about the material would be willing to complete the time-consuming survey, which consisted of about sixty open-ended essay questions. Thus, it is often those with the most extreme views who are willing to participate in these types of studies. Additionally, research methods for studies in which statistics are presented as an estimate of population value require the use of a randomly selected sample. However, Hite's survey was sent to a number of women's groups, many of which were considered to be feminist organizations. Hite continued to use similar methods for each of her studies and has repeatedly drawn criticism for presenting statistics and developing theories using samples that are not representative of the population.

HITLER, ADOLF
1889–1945

As the leader of Germany's Third Reich in the 1930s and 1940s, Adolf Hitler developed a totalitarian fascist state dedicated to imperialist expansion of a pure German race. Hitler and his anti-Semitic, supra-nationalistic National Socialist German Workers' Party (Nazi Party) was ultimately responsible for millions of deaths during the Holocaust and a massive refugee crisis in Central and Eastern Europe during World War II (1939–1945).

Hitler was born on April 20, 1889, in Braunau am Inn, Austria, and spent his younger years in Linz, Austria, and in Vienna. Hitler was not a good student; he left the Gymnasium without graduating and failed to be accepted as an art student at Vienna's Academy of Fine Arts. This failed career move left Hitler a lonely and distraught young man. While in Vienna in the years leading up to World War I (1914–1918), Hitler developed anti-Semitic tendencies, most likely fed by his envy of affluent Jewish citizens during his years of extreme poverty and destitution as well as the influence of Vienna's Lord Mayor who publicly supported anti-Semitic policies. In 1913 Hitler moved to Munich where he lived until the war broke out and he volunteered to serve in the German Army. During the war, Hitler was injured twice, once in 1916 and again in 1918, the second time as a victim of a gas attack. For his bravery and valor, he earned the Iron Cross twice and was promoted to the rank of corporal. Hitler returned to Munich after the war, dispirited, disillusioned, and angry over the Versailles settlement. Like many young returning soldiers, Hitler believed that Germany's new liberal government should not have signed the Treaty of Versailles. The Treaty forced Germany to accept full responsibility for starting the war, stripped Germany of its colonies, required that it pay heavy reparations to the Allied powers, demilitarized a large portion of its western territory, and reduced its military numbers substantially. Hitler believed that these terms unjustly punished Germany and joined the right-wing, nationalist German Workers' Party in 1919, the forerunner of the National Socialist German Workers' Party, to work toward a reversal of the treaty.

By 1920 Hitler was the leader of propaganda of the growing German Workers' Party, and in 1921 he became the führer (leader) of the organization, now called the Nazi Party. The Nazis at this time were still a very small splinter party, but gained notoriety with their failed Munich Hall putch in 1923, after which Hitler served nine months in prison. During his incarceration, Hitler wrote his famous memoir and political treatise Mein Kampf (My Struggle) where he condemned democratic systems and blamed Europe's Jewish population for what he considered to be Germany's crisis of morality and modernity. The issue of race and its intimate connection to political institutions that stood as symbols of a vanishing collective identity became the focal point of Hitler's theory of fascism. In the tradition of other “philosophers of race” such as Comte de Gobineau and H. S. Chamberlain, Hitler believed in the natural inequality of human races. The white race, he argued, was superior to all others, with the Teutonic race as the most civilized and advanced. Because Hitler believed that the demise of the human race begins with an intermingling of races that causes social instability through a crisis of identity, he called for social, political, economic, and cultural policy to protect the purity of German blood first and foremost.

This belief in ethnic community as the foundation of the nation led Hitler to be suspicious of the Jews' lack of a homeland. He referred to them as “parasites on other peoples” and fervently believed that their infiltration into European society needed to be halted immediately. Hitler was equally suspicious of liberal doctrines of “equality” and “liberty” because, he argued, they only allowed Jews to exploit Europe's gullibility about their true intentions to take over European society. Hitler pointed to the Jewish origins of many Soviet revolutionary leaders, their support of trade unionist activities, as well as their overarching presence in business, finance, banking, and stock market sectors as evidence of Jewish infiltration. Therefore, for Hitler and the Nazis, Jews represented the gravest threat to the Aryan race because of their prominent roles in the development of liberal capitalism and socialism, two modern ideologies that threatened Germans' collective identity. In this way, Hitler's brand of fascism was both anti-Marxist and anti-Semitic, for the two were inextricably intertwined in his mind. Hitler's race doctrine was thus used as an instrument of defense against the inescapable degeneration of Aryan civilization. Only through active destruction of racial inferiors, defined by Hitler to be primarily Jews but also included Slavs, Roma, homosexuals, political dissidents, and disabled people of all ethnicities, could Germany be saved. This dedication to action, outlined in Mein Kampf, provided the philosophical foundation for the Holocaust and was responsi-
ble for the deaths of approximately 6 million Jews and 3 million other “degenerates” during the Nazi era.

THE RISE OF HITLER’S NAZI PARTY

After his release from prison, Hitler worked throughout the 1920s and 1930s on building a mass political movement. Nazi Party propaganda publicized Hitler’s ideas of a Jewish and socialist threat by arguing that both were responsible for Germany’s inflationary crisis that was, in fact, due to the Republic’s printing of monies to make reparations payments, a number of attempted coups, and the French occupation of the Ruhr. Between 1925 and 1928 alone, Nazi Party membership jumped from 27,000 to 108,000 active supporters. On the eve of the United States stock market crash of 1929, the National Socialists were active in parliamentary politics, earning 810,000 votes in the 1928 election and occupying twelve seats in the Reichstag.

The Nazis gained considerable momentum as economic crisis intensified with the onset of the Great Depression in the early 1930s. The major challenge for Hitler and the Nazis was to prevent unemployed workers from becoming socialist revolutionaries, and so their propaganda vilified trade unionism. Hitler further targeted socialists as enemies of the German nation because the Social Democratic and German Communist parties had voted against war credits during World War I and a revolutionary German socialist government had signed the armistice authorizing Germany’s capitulation in 1918. Nazi propaganda became more openly anti-Semitic at this time too, with Hitler firmly blaming Jews for Germany’s national crisis through their perpetuation of immoral capitalist practices. At the same time, Hitler pointed to the inability of Weimar’s parliamentary system to respond adequately to the Depression. Disagreements between coalition factions and internal divisions in the Social Democratic Party, Germany’s largest political party, led to a general paralysis in how to finance unemployment relief. Hitler promised voters the eradication of unemployment, the creation of a welfare state, and a nationalistic program of industrial, agricultural and governmental cooperation. With this platform, Hitler succeeded in winning 6.4 million votes and 107 parliamentary seats in the 1930 election. Despite this incredible success, the Nazis still had yet to earn the support of disenchanted industrial workers. Most of their electoral support came from traditional right-wing voters—members of the petty bourgeoisie and agricultural workers—and young, new voters. Hitler successfully converted young Germans to National Socialism through the creation of youth organizations and events such as parades and political rallies that fostered a sense of national community and presented the Nazi Party as one that would unify Germans and resurrect a lost Germanic empire. By 1931 industrialists responded en masse to Hitler’s anti-Marxist platform and his assertions that what would be good for the German people would be good for German industry and joined the Nazi crusade. In the 1932 election, the Nazis won 230 Reichstag seats, the most seats ever held by a single political party in German history, though they still did not enjoy an electoral majority.

On January 30, 1933, President Paul von Hindenburg appointed Hitler the chancellor of Germany. The Reichstag fire on February 27, erroneously believed to have been set by representatives of the German Communist Party (KPD), allowed Hitler a further opportunity to warn Germans of an impending socialist revolution that would destroy the German Fatherland. With heavy pressure from Hitler, Hindenburg then issued an emergency decree “for the Protection of People and State” that restricted personal liberties, extended the government’s legal ability to obtain warrants for house searches, confiscate private property, and monitor citizens’ postal and electronic communications, and allowed all KPD Reichstag members and other leading anti-Nazis to be arrested. In March 1933, the Reichstag approved the implementation of the Enabling Act that granted Hitler dictatorial powers for four years and officially destroyed the Weimar constitution. A plebiscite in late 1933 confirmed the Nazis’ control and, with Hindenburg’s death in August 1934, Hitler became Germany’s new führer.

THE DEVELOPMENT OF THE THIRD REICH

Throughout the mid-1930s Hitler successfully established a strong centralized government that exercised unlimited authority to direct the development of the Third Reich, as Hitler titled his new German empire. The state fulfilled its promises to solve Germany’s national crisis by guaranteeing universal employment (with the caveat that all citizens must work), extending social welfare programs including old age pensions and economic protection of mothers and children, nationalizing industry, introducing land reform, and institutionalizing the creation of physical fitness programs to promote national health and vigor. The government also solidified its political power by controlling all forms of media, forming a national army, institutionalizing a “social contract” that emphasized the symbiotic dutiful relationship between state and citizen (not of individuals to one another as in the Marxist model) primarily through the heavy use of propaganda, parades, and other public displays of nationalism. In addition, the state re-aligned the education system’s philosophical foundation to fuse “German” moral values of obedience and deference to authority with Hitler’s race doctrine and
HIV

developed a legal system that defended the Nazis' use of terror and coercion to create a totalitarian state.

The Nazi government also worked to expose and eradicate Jews from German society. The 1935 Nuremberg Laws, which included the Reich Citizenship Act and the Act for the Protection of German Blood and German Honor, enacted a number of anti-Semitic laws allowing only ethnically “pure” Germans citizenship rights. These acts categorically excluded Jews from civil and public service and prohibited Germans and Jews from marrying and forming other intimate relationships in order to preserve the Aryan blood line. The Nuremberg Laws were the first step in the eventual ghettoization and murder of millions of European Jews in concentration camps during World War II.

HITLER AND WORLD WAR II

After securing Germans' loyalty through his propaganda of equality and community, Hitler set out to expand Germany's borders through imperialist wars. First he instituted compulsory military service and re-militarized the Rhineland in blatant violation of the terms of the Versailles Treaty. He then began the process of uniting all Germanic peoples into a Grossdeutschland (“large Germany”) with the annexation of Austria in early 1938. Participants of the Munich Conference in late 1938—Britain, France, and Italy—then allowed Hitler to annex the Sudetenland, the northwestern portion of Czechoslovakia, bringing the large German minority population there under Nazi control. Hitler's imperialist intentions became more apparent in early 1939 when he invaded Bohemia-Moravia and established a Nazi puppet state in Slovakia. Britain and France then realized that their policy of appeasement toward Germany was failing and prepared for war. World War II broke out in September 1939 when Hitler invaded Poland, a move the Western allies viewed as a blatant violation of Poland's right to national self-determination.

Hitler invaded Poland for what he called “Lebensraum” (“living space”). His goal was to expand Germany's empire through the annexation of Polish territory, the murder of Polish Jews and political dissenters, and the resettlement of the German Volk (the “people”) into Poland. This expansion, Hitler argued, was an essential component of German national growth because it would allow the peasant class to maintain its identity as the foundation of the nation through successful cooptation of agricultural land that was untouched by the vagrancies of modernization. This policy of acquiring Lebensraum provided the practical justification for the Holocaust. Poland was an easy target for Hitler because it housed the largest Jewish population in Europe and represented a traditional subordinate territory of the two old German empires: the Prussian and the Habsburg.

In the early years of the war, Hitler succeeded in either conquering or establishing Nazi puppet states or allies on most of the European continent including France, Holland, Belgium, Denmark, Norway, Finland, Austria, Poland, Czechoslovakia, Hungary, Romania, Croatia, Yugoslavia, Bulgaria, Albania, and Greece. The United States' entry into the war in December 1941 as an ally of Britain and the Soviet Union turned the tides of battle and they succeeded in defeating Germany in May 1945. Recognizing Germany's imminent defeat, Hitler committed suicide in Berlin on April 30, 1945.

HIV

The human immunodeficiency virus (HIV) is part of a family of retroviruses that have the capacity of reproduction from RNA in the nucleus of a helping cell of the human immune system. Using enzymes—chemical substances in the human organism that enhance reactions without intervening in them—the virus breaks through the cell membrane to the nucleus, where it is reproduced. Infection with HIV leads to the disease known as AIDS.
The origin of HIV is unknown, but it is widely understood that it is a mutation of a similar retrovirus, such as the simian immunodeficiency virus. It is speculated that the virus developed the capacity to infect human beings through the practice of ingesting raw meat or blood in religious rituals in isolated parts of Africa. Even though the first AIDS cases were reported in Africa in the early 1980s, several known cases were before this date.

THE DISCOVERY OF HIV
At the beginning of the AIDS epidemic, the virus was initially called human T-lymphotropic virus type III (HTLV III) by the U.S. research group under the leadership of Robert Gallo. The virus was also discovered at about the same time by researchers at the Pasteur Institute of France under the leadership of Luc Montagnier, who named it lymphadenopathy-associated virus (LAV). Following an international controversy between the two researchers, who both claimed credit for the discovery, the name HIV was agreed upon.

By 1982 it had been established that HIV had caused the destruction of the immune system of numerous individuals, rendering them susceptible to infections that produced a combination of diseases, such as Kaposi sarcoma and pneumonia. This overall disease process was called acquired immunodeficiency syndrome (AIDS). By this time it had also been established that the virus was transmitted via body fluids, such as blood and semen.

A number of factors—including the migration of infected people to populated zones, overpopulation in certain communities, difficulties in access to medical care, and ignorance of the disease—led to the infection becoming a pandemic by the end of the 1980s. The first AIDS cases in the United States were reported in the summer of 1980, when the Centers for Disease Control and Prevention (CDC) reported several cases of young males with opportunistic infections and a compromised immune system. The number of reported AIDS cases then began to increase in a geometrical way through the entire world. According to the CDC, the cumulative estimated number of diagnoses of AIDS through 2003 in the United States was 929,985. Adult and adolescent AIDS cases totaled 920,566, with 749,887 cases in males and 170,679 cases in females. The remaining 9,419 cases had occurred in children under age 13. At the end of 2003, it was estimated that 1,039,000 to 1,185,000 persons in the United States were living with HIV/AIDS and that between 24 and 27 percent were undiagnosed and unaware of their condition.

TESTING FOR HIV
There is a test to detect the presence of HIV antibodies. A more specialized test, the polymerase chain reaction (PCR) test, can identify the virus, but it is only used for special cases or research due to its high cost. For the general public, the ELISA test is used, which only detects the presence of HIV antibodies. This test is highly sensitive for negatives, which is why it is commonly used for screening possible cases. But because of this sensitivity, ELISA tests that are positive must be confirmed with a more accurate test, called the Western blot. Both tests are readily available through public health services, and many health community-based organizations provide the test at outreach activities in the communities.

TREATMENT AND PREVENTION
As of 2007 there was no available vaccine for HIV. More than 95 percent of all new infections were in developing countries, making HIV/AIDS one of the most serious threats to global health and global development. Many believe that only a vaccine will stop the spread of the infection. Developing a vaccine will thus represent a huge milestone in the AIDS epidemic, and several clinical trials are being developed in different countries. However, the versatility of the virus and other concerns have made this a difficult task.

Due to the nature of HIV infection and the lack of a cure or vaccine, the only way to address the epidemic is by means of prevention. Primary prevention programs target vulnerable populations by means of culturally and competent interventions designed to help people avoid being infected. Because the virus is transmitted by contact with fluids, sharing infected needles for drug use, having sexual intercourse without protection, and mother-to-infant transmission are the main venues for the virus to be introduced to human beings. Important primary prevention interventions have been developed and evaluated in the United States and other industrialized countries, and these are being transferred to other communities around the world. These prevention programs include education about the virus, condom distribution, clean needle distribution for drug addicts, and peer counseling, and they have slowed the spread of HIV. The basic idea is that by learning the ways the virus is transmitted and by developing personal and social skills that protect and empower at-risk minority communities, it is possible to stop the spread of the infection.

Advances in treatment have yielded important new AIDS therapies, but the cost and complexity of their use put them out of reach for most people in the countries where they are needed the most. In industrialized nations, where the drugs are more readily available, side effects and increased rates of viral resistance have raised concerns.
about the long-term use of these therapies. Since the mid-1990s, HIV infection has spread most rapidly among women, children, and sexual minorities. Both in the United States and in developing countries, the incidence of HIV infection has had a disproportional impact on communities of color. Efforts at primary prevention must therefore take into consideration the social and cultural context and meanings of what are known as “high-risk behaviors.”

It is also important of course to pay attention to those already living with HIV/AIDS, with the goal of providing them access to care and secondary prevention. By engaging people living with HIV/AIDS in appropriate treatment, the quality of life of these individuals can be enhanced. This level of treatment will also reduce the continuing transmission of the infection. For this to happen, the human rights of people living with HIV/AIDS need to be protected. This will encourage them to get tested and receive medical and social care.

THE STIGMA OF AIDS

Jonathan Mann, the founding director of the World Health Organization’s Global Programme on AIDS, described the HIV epidemic as more than just a biological disease. It is also a social phenomenon that he identified as potentially explosive because it is an epidemic of social, cultural, economic, and political responses to the disease. This social epidemic is characterized above all by exceptionally high levels of stigma, discrimination, and at times collective denial.

The concept of stigma dates to ancient Greece, where it was used to describe persons who had been involved with certain bad deeds, for which they were distinguished from others by the application of bodily marks or tattoos. People so marked were to be avoided by the general populace. The concept has also been associated with an unnatural mark in the bodies of saints, a mark made with a hot iron on the flesh of slaves, a bad reputation, and even a physical dysfunction. Some authors have described stigma as a social construction associated with the recognition of a “difference” based on a specific characteristic, which is used to devalue the person who possesses that characteristic. All of these definitions share the idea that a stigma is the negative evaluation of a particular difference that may be identified in a person. The stigma associated with AIDS has become the biggest obstacle for HIV/AIDS prevention, because it hinders the possibility of dignity and access to care for people living with the infection.

HMONG

Hmong society is based on outmarrying patriclans within which ideals of fraternal hospitality are maintained. Within clans, lineages are clustered around the worship of a common ancestor. Cultural divisions cut across clans to mark different groups of Hmong by dialect, female costume, and architecture. Shamanism, ancestor worship, and a belief in nature spirits form a profound religious complex. There is no traditional form of Hmong writing, but a missionary-invented romanized script is widely used.

Traditionally the Hmong were shifting cultivators of forest at altitudes of 3,000 to 5,000 feet in the mountains of southern China and the neighboring countries of Indochina, with an economy based on the production of dry rice, maize, and opium as a cash crop, some hunting, and animal husbandry. The household was the unit of production, and hamlets were often settled by members of the same local descent group. There was no hereditary position of political authority, nor any political authority higher than the village. Houses were built on the ground out of wood.
The Hmong form perhaps a third of the Miao national minority of China, which numbered 9.6 million in 2002. Although unknown in Chinese records under the Hmong ethnonym, under the name of Miao it is clear that their history in China is an ancient one, and was characterized by a series of violent clashes against centralized imperial authority.

During the last half of the nineteenth century, Hmong from China migrated into Burma (Myanmar), Thailand, and the northern parts of Laos and Vietnam, after the failure of rebellions in south China and increasing pressures on scarce land resources. In north Vietnam, the Hmong were caught up in the First Indochina War (1946–1954) and were instrumental in the Viet Minh victory against the French at the battle of Dien Bien Phu (1954).

During the civil wars in Laos from 1962 to 1973, Hmong were divided along clan and regional lines between support for the rightist parties and for the socialist Pathet Lao. As porters, guides, spies, and fighters, they were crucial to the war effort fought mostly in sensitive border regions; many became regular or irregular troops under General Vang Pao of the Royal Lao Army. Casualties were heavy.

With the fall of Laos in 1975, more than 100,000 Hmong fled Laos for Thailand, where they were housed in five refugee camps along the border, from which they have mostly been resettled in third countries. A large number refused resettlement because they were led to believe they would be needed to retake Laos, where a small resistance movement continues with variable support from elements of the old counterinsurgency military establishment. Formal recognition of their support for the American war effort in Indochina was won in the Hmong Veterans' Naturalization Act of 2000, which allows special consideration for irregular Hmong ex-soldiers.

A new culture emerged in the refugee camps as farming people with newfound leisure produced new forms of culture for sale to the outside world that told of their history and sufferings, such as embroidered story-cloths and the new music championed by the leader of a messianic movement. The Hmong came under increasing Christian influence in the camps, which has led to serious divisions in the community.

Outside China the Hmong have been estimated at 153,955 in Thailand, 315,000 in Laos, 787,604 in Vietnam, and perhaps 2,000 in Burma. Overseas population figures are estimated at 15,000 for France, 1,800 for Australia, 2,000 for French Guyana, 1,200 for Canada, 250 in Argentina, 92 in Germany, and 186,310 in the United States. Resettled Hmong have sought to regroup in areas of better economic opportunity and to join larger groups of Hmong. In the early 1990s, half the Australian Hmong population moved to North Queensland to farm bananas. By 2003, all 150 Hmong settled in New Zealand had joined the Australian Hmong. From 1981 to 1983, 20,000 Hmong arrived in the Central Valley of California, and some 20,000 moved again in 1998 from California to Minnesota.

American Hmong are concentrated in California, Minnesota, and Wisconsin. Particular cultural problems have been caused by ritual animal sacrifices in cases of illness and at funerals, which traditionally take place at home. Pressing social issues include the changing position of women, underage marriages, and the growing prevalence of youth gangs. Although the majority of Hmong refugees find unskilled work or remain on social welfare, there have been many success stories, with the emergence of Hmong singers and poets, publishers, academics, and politicians. The fragmentation of families between two or more countries remains an issue for most of the older generation. Clan organization has proved a vital adaptation mechanism, with lending pools and mutual help societies formed. Some return visits to Laos and Thailand have taken place, remittances are often sent home, and some brides have been sought from Thailand, Laos, or China. Overall there has been a huge change of consciousness as the Hmong recognize themselves as a global, albeit fragmented, community and adopt new forms of communication, such as the Internet and telephone, with facility.

HO CHI MINH
1890–1969

Ho Chi Minh played a pivotal role in the global processes of anticolonialism and decolonization that accompanied World Wars I and II. His leadership has become an enduring symbol of third world resistance to the West during the twentieth century.
Ho Chi Minh was born in on May 19, 1890, in central Vietnam. Biographers have estimated that he used over fifty aliases during his career. He was educated in the Confucian classics, instructed in three languages (Chinese, French, and romanized Vietnamese), exposed to a modern multidisciplinary curriculum, and steeped in Vietnamese history. In 1908 he was expelled from the National Academy for his involvement in a peasant demonstration.

In 1911 Ho Chi Minh resolved to leave Vietnam to experience life in France. He secured employment with a steamship company and traveled widely to ports in Europe, Africa, Asia, and the United States. He claimed to have lived in New York in 1912. In 1913 he moved to London, where he studied English, and in 1917 he returned to France.

In 1919 Ho Chi Minh gained notoriety when he presented to the major powers gathered at the Versailles peace conference a petition arguing that Woodrow Wilson’s Fourteen Points should be applied to the colonial peoples in Indochina. This document was signed “Nguyen Ai Quoc,” a pseudonym he used for the next quarter century. In 1920 Ho Chi Minh joined a breakaway faction of the French Socialist Party that joined the Communist Third International.

In 1923 Ho Chi Minh moved to Moscow and began a career as an agent of the Communist Third International (or Comintern). He was assigned to China in 1924. In February 1930 he presided over the founding conference of the Vietnam Communist Party. Ho Chi Minh’s revolutionary career was interrupted by his arrest and detention by British authorities in Hong Kong (1931–1933). He resumed work with the Comintern in Moscow after his release, and in 1938 he was posted back to China.

In February 1941 Ho Chi Minh returned to Vietnam after an absence of three decades. In May of that year he founded the anti-Japanese Viet Minh Front. He was detained by Nationalist authorities in southern China the following year and released in 1943. While in China, he made his first contacts with U.S. officials. He professed admiration for President Franklin Roosevelt’s anticolonial sentiments. In 1944 Ho Chi Minh reached an agreement with the Office of Strategic Services (OSS) in China. He agreed to supply intelligence and assist in the rescue of downed pilots in exchange for OSS assistance to and training of Viet Minh troops.

In August 1945 the Viet Minh seized power, and on September 2 Ho Chi Minh declared Vietnam independent, citing the opening words from the American Declaration of Independence. He used his OSS contacts to convey messages to President Harry Truman requesting support. In 1946 Ho Chi Minh twice offered the United States access to Cam Ranh Bay.

Ho Chi Minh led the Vietnamese people in a successful eight-year war to expel the French (1946–1954). From 1954 until his death on September 2, 1969, he held the twin positions of head of state and chairman of the party in North Vietnam. In reality power over domestic affairs was held by the party general secretary and senior members of the politburo. Increasingly he focused his energies on foreign affairs and national reunification.

Ho Chi Minh was both a Communist and a nationalist. His brand of communism was more pragmatic than doctrinaire, while his patriotism was uncompromising. In Ho Chi Minh’s words, “Nothing is more precious than independence and freedom.”

HOBBES, THOMAS
1588–1679

Thomas Hobbes was the first influential philosopher to apply the methods of Enlightenment science to politics. At the age of twenty, he was hired as a tutor for the son of William Cavendish (1640–1707), the first Earl of Devonshire, and he received support and employment from the Cavendish family throughout his life. In 1628 Hobbes published a translation of Thucydides’ (c. 460–c. 401 BCE) History of the Peloponnesian War, and in various visits to the Continent he befriended and engaged in discussions about mathematics and science with the luminaries of the day, including Galileo Galilei (1564–1642), Pierre Gassendi (1592–1655), and Marin Mersenne (1588–1648).

He authored his first book, Elements of Law (1640), at age fifty-two. Sounding themes that would become familiar throughout his work, he declares that humanity’s natural state is a state of war and that only by divesting themselves of their natural rights and transferring those rights to a sovereign can people ensure their physical safety. Shortly thereafter, in anticipation of the English Civil War (1642–1648), Hobbes fled to France, fearing...
that a treatise that justified the king’s prerogatives would bring retribution from the parliamentarians.

While in France he tutored the future Charles II (1630–1685), critiqued René Descartes (1596–1650), wrote De Cive (an expanded version of the second part of The Elements of Law), and authored and published his most important work: Leviathan (1651).

In Leviathan, Hobbes asserts that humanity’s natural condition is characterized by two kinds of equality. First, everyone has the ability to kill. Second, everyone is equally prone to believe that they are more wise than everyone else. This leads to competition, mistrust, and a desire for glory, which in turn makes people’s natural condition a state of war. The state of war for Hobbes is as much a milieu as it is actual fighting and it is the background condition of all human relations.

The difficulties that attend people’s natural condition, in combination with their natural desire for self-preservation, means that they have a natural right to anything and everything. However, reason (and experience) leads one to the conclusion that retaining this right can only lead to a life that is “solitary, poor, nasty, brutish, and short” (Hobbes 1994, p. 76).

The solution to the war of all against all is a social contract. By giving up their natural right to anything and everything, people create a sovereign who commands precisely that right: an absolute sovereign. Creating this sort of sovereign is the most effective way to ward off the state of nature because an absolute sovereign overawes those who might be tempted to reclaim their natural right. Indeed, the leviathan is, citing Job, “King of the Proud.” In addition, a single decision maker eliminates the potential for internal disputes and undivided power prevents one sector of society or government from withholding resources from another.

The sovereign power is not itself party to the social contract because a covenant is only valid if it has the power of the public sword behind it. In effect, no subject can bring redress against the sovereign, because the sovereign itself is the only party to which redress can be brought. The sovereign is therefore not obligated to act in a way that is beneficial to the individuals who created it. Instead, having contracted their will to the sovereign, the decisions and punishments of the sovereign amount to decisions and punishments that a subject inflicts on him or herself. However, the sovereign is obligated to protect the commonwealth from internal and external enemies (by making law and making war) and there are incentives for the sovereign to act in ways that are beneficial to subjects. Hobbes also suggests that the sovereign cannot expect individuals to literally kill themselves on command. The crucial point to keep in mind is that even a bad government is preferable to the state of war or a government prone to dissolution.

In Leviathan and in his other works, Hobbes uses the principles of science and mathematics to ascertain the fundamental basis of politics. This approach understands the world as composed of bodies in motion and requires developing and working from careful definitions of key concepts. The result is a mechanism rendering of human relationships that imagines human bodies and desires in geometric relation to one another. This is not to say his works are gauged only for the scientific reader. Instead, Hobbes combines science and rhetoric in an attempt to affect the politics of his time.

In 1652 he returned to England, having offended Parisian royalists who took exception to his attack on Roman Catholicism. Hobbes envisioned a three-part description of political existence consisting of body, man, and government. The Elements of Law and Leviathan describe most of the salient features of the second and third parts of this scheme and De Cive is devoted exclusively to the third, but he set out to fully develop the first two parts, writing De Corpore (Of Body, 1655) and then De Homine (Of Man, 1658). He also wrote a history of the English Civil War, Behemoth (1668). His work was widely read and debated during his lifetime. Some of his mathematical assertions were successfully rebutted and his stated commitment to Christianity and God was and is a matter of dispute.

By grounding government in a contract between equals, as opposed to divine sanction, Hobbes initiates a discussion about the purposes and character of government that defines much of modern political thought. His most notable and direct influence was on John Locke and Jean-Jacques Rousseau, and his influence on certain forms of conservatism endures.

HOBOS

The term hobo was used to describe homeless people who moved around in order to find temporary work in the United States during a cycle of depressions between 1879 and 1939. The term was often conflated with the terms tramp and bum. Contemporary uses of the word are rare. Similar people are now most often called homeless or migrant workers. The most famous definition of the hobo is said to originate from the Chicago anarchist Ben Reitman who stated that a hobo moves and works, a tramp moves and doesn't work, and a bum stays still and does not work. It is unclear from where the name originates. Some claim that it is derived from the name hoe boy—an agricultural worker. Another theory is that hobo is a derivation of the Latin homo bonas (good man).

Despite such attempts to differentiate hobos from tramps, contemporary observers tended to refer to the mobile homeless as tramps and hobos interchangeably. Most were male, white, and American-born, but there were significant numbers of black and female hobos as well. In 1911 one researcher suggested a population of 350,000 hobos. A 1906 estimate put the population at 500,000.

Hobos and tramps were most likely to travel alone either on freight trains or on foot. Because such train travel was illegal, it was also extremely dangerous. They would travel between, on top of, or underneath carriages. As they often had to get onto the train while it was moving, they were frequently injured or killed in the process. Railroad police were also known to deliberately throw hobos off moving trains. Estimates of annual death and injury to hobos and tramps ran as high as 5,000. Hobos most often worked in construction, agriculture, and mining. Indeed, the newly industrialized agriculture of the American West depended on the ability of migrant laborers to follow harvests from apples in Washington State to beets and grapes in California. Others followed the wheat harvest through the Midwest from Kansas to the Dakotas.

Between jobs hobos would gather on the outskirts of urban areas alongside railroad tracks in places known as hobo jungles. They would also use police stations, lodging houses, “flop houses” (a place offering very cramped, cheap lodging for transients, usually men), and missions. These would normally be located along an area called the Main Stem—a part of town associated with lodging for the homeless as well as employment agencies, cheap cafes, and soup kitchens.

Following the recession of 1879 hobos were subjects of a moral panic known as the tramp scare. They were generally represented as being foreign-born, lazy, and politically subversive. Newspapers called for them to be jailed, forced into work camps, sterilized, or even killed. Eugenicists believed them to be members of an “inferior” racial group who favored a nomadic lifestyle. By World War II (1939–1945) the term hobo had been replaced by the term migrant, which had been used in the 1930s to refer to those displaced by the Great Depression and the Dust Bowl in the American South and Midwest. Since World War II people who would have been called tramps or hobos in the early part of the twentieth century have been referred to most often simply as the homeless. Indeed, the earlier figures of hobos and tramps became romantic figures. Charlie Chaplin, Jack Kerouac, and others used the hobo figure to question some of the assumptions about “normal” life in the United States.

HOLOCAUST, THE

“The Holocaust” is the most common name for the systematic destruction of almost 6 million European Jews under German National Socialism between 1933 and 1945. Holocaust, from the Greek holokauston, means a burnt sacrifice or offering. Because the events of the Holocaust were no such thing, however, many prefer other terms, including the Hebrew Shoah (calamity) or “genocide of the European Jews.” The term genocide (murder of an entire ethnic group) was coined during World War II (1939–1945) by the Polish exile lawyer Raphael
Lemkin to describe the murderous program Germany was carrying out, particularly in occupied central and eastern Europe; since then genocide has been used to refer to numerous other historical programs of mass ethnic-based extermination.

JEWS AND THE NAZI REGIME

The Nazi regime never made a secret of its anti-Semitism, if there is nevertheless substantial debate about how early, public, and explicitly murderous were its intentions to make Europe Judenrein (free of Jews). Vilification and scapegoating of Jews was certainly a central feature of Nazi rhetoric throughout the 1920s. Following the Nazi seizure of power in Germany in January 1933, the regime instituted a boycott of Jewish businesses. Soon thereafter Jews were dismissed from the civil service, and strict quotas were placed on Jewish presence in schools. In May 1933 libraries were purged of “decadent” materials, Jewish and otherwise, which were burned in great pyres in public squares.

As discrimination against Jews escalated in the following years, authorities felt the need for a more precise legal definition of “Jew,” which they produced in the September 15, 1935, Nuremberg Laws for the Protection of German Blood and German Honor and the Law of the Reich Citizen. The Nuremberg Laws defined Jews as those having at least three Jewish grandparents; those with one or two Jewish grandparents were defined as Mischlinge (mixed breeds). The laws prohibited marriage between Jews and “Aryans” and declared civil and political rights only for “Germans.” Despite many generations of patriotic commitment and a high degree of social integration, including often enthusiastic participation in the German military during World War I (1914–1918), Jews were no longer considered German.

A more vigorous stage of persecution began on November 9, 1938. Following the murder of a German diplomat in Paris by a Jew, the Nazi regime sponsored an enormous nationwide pogrom against Jews often referred to as Kristallnacht (Night of Broken Glass). In two days more than 7,000 Jewish-owned shops and businesses were destroyed, more than 1,500 synagogues (almost every synagogue in the country) were burned, more than 100 Jews were killed, and more than 30,000 other Jews were imprisoned in the so-called concentration camps that had been set up since the first days of the regime for holding political opponents and others.

World War II began on September 1, 1939, when the German army invaded Poland. With the progress of war and the occupation of vast portions of eastern Europe, the Nazis’ murderous programs entered a new phase. Chancellor Adolf Hitler explicitly endorsed a large program of “euthanasia” for “undesirables,” mainly the mentally and physically handicapped, though the definition of “undesirable” extended to include homosexuals, prostitutes, Jehovah’s Witnesses, and Sinti and Roma peoples (Gypsies), among others. In July 1941 Hitler also explicitly discussed the so-called Einsatzgruppen (operational forces). These special units engaged in systematic, though cumbersome, mass murder of Jews and partisans in the occupied territories, often by machine-gunning large groups of people gathered to dig their own graves.

Nevertheless, given the stresses and expenses of such a program, Nazi planners sought other, more efficient means for killing large numbers of Jews as well as for disposing of their bodies in a more sanitary way. Experimentation thus continued with various forms of mobile death squads and subsequently with specially designed gas chambers as well as large-scale crematoria. The regime built and expanded camps to carry out these latter innovations. The extent of these practices was systematized and expanded following the Wannsee Conference of January 20, 1942, where Nazi leaders met and empowered such functionaries as Adolf Eichmann to coordinate the vast transport of Jews to the death camps, defining what they euphemistically called “the final solution to the Jewish problem.” In July 1942 SS leader Heinrich Himmler ordered the evacuation of the many ghettos the Nazis had set up in eastern European cities to segregate and control Jewish populations. Most of these evacuations—most notoriously of the Warsaw ghetto—involves transport to “extermination camps” (Verwöhnlagern) in such places as Auschwitz-Birkenau, Treblinka, Belzec, and Majdanek. Best estimates are that approximately three million Jews died in the death camps, in addition to the millions of others who died in concentration camps, by mass killings, and of disease, hunger, desperation, and murder.

SOCIAL SCIENCE AND THE HOLOCAUST

Most accounts from a social sciences perspective emphasize how sociologists, psychologists, and others have sought to explain the Holocaust as well as how social science was necessarily influenced and challenged by the ramifications of the Holocaust. In focusing on the role the Holocaust has played in social science, however, we overlook the role social science played in the Holocaust. For indeed social theory and research of various kinds was an important part of the intellectual milieu from which National Socialism arose. National Socialist ideologues drew explicitly on social Darwinism and eugenics, which were prominent themes across the political spectrum both in Germany and elsewhere in the first decades of the twentieth century. In Germany in particular social theory helped define a climate of “radical conservatism.”
Prominent thinkers, such as Oswald Spengler, Werner Sombart, Arnold Gehlen, and others, helped define a mood of cultural discontent and suspicion of liberalism, which contributed to the failure of the Weimer Republic. Indeed many such figures remained in Germany throughout the Nazi years, some—for instance, Hans Freyer—even assuming positions of power in Nazi academe and beyond. Many of these intellectuals, as well as those trained under them during the Nazi period, were rehabilitated after the war and became prominent figures in post-war thought (e.g., Helmut Schelsky).

Given the predominance of both Marxism and Jews in German sociology during the 1920s, moreover, many falsely assume that the Nazis rejected the social sciences. That was not entirely the case. The Nazi regime used the social sciences for a variety of purposes, drawing great power from the advanced state, for instance, of German managerial science. In the early years of the regime, the Swiss psychoanalyst Carl Jung collaborated with Matthias Goering, brother of the Nazi propaganda minister and Hitler confidante Hermann Goering, on the formation of a German Psychoanalytic Society “free of Jewish influence.” The sociologist Theodor Geiger’s work was part of the discussion of Nazi sterilization and euthanasia programs. Social scientific work on regional planning was useful to the formation of occupation policy in the East, as were area specialists, who drew on and contributed to German Ostforschung (research on the East), which incorporated geographical, economic, and sociological approaches. Freyer, director of the German Scientific Institute in Budapest, and his assistant Schelsky contributed to cultural propaganda aimed at the Hungarian intelligentsia. The so-called Inlandsnachrichtendienst (Domestic Information Service) employed large numbers of social scientists to gather public opinion and other data. While the regime had chased large numbers of leading scholars into exile, remaining Nazi scholars sought to combine traditional social theory (Gesellschaftslehre) with a new racist anthropology (Volkswisellehre) into a “unified theory” (Gesamtheitslehre). As in law, medicine, literature, and other institutional spheres, then, portions of the social sciences as well as some of their members were associated with, were used by, and supported the Nazi regime, and the contemporary disciplines neglect examination of this legacy at their peril.

EXPLAINING THE HOLOCAUST

Social scientific efforts to explain the Holocaust directly have been few and far between. In the first place, the unprecedented scale of industrial killing the Nazis undertook as well as the unfathomable mass of cruelty they sponsored in some sense defy explanation and are grasped more readily in the philosophical vocabulary of radical evil. Indeed cultural theorists have often described the Holocaust as an event “beyond the limits,” which include those of comprehensibility as well as representability. In the second place, sociology and political science, some have argued, are better suited to explaining conditions and structures rather than events, particularly events considered unique in a sense beyond the usual one in which all historical events are unique. But part of the reason is that the contemporary association of National Socialism and World War II with the Holocaust was not always as central as it is in the early twenty-first century. For at least twenty years after 1945, most social scientific and historical accounts saw the Judeocide as a consequence of rather than as the centerpiece of National Socialism.

To be sure, a wide variety of theory has sought to explain the rise of National Socialism in Germany and the extreme violence it produced. Two major axes of argument characterize most of this literature. The first is between theories that see National Socialism as a variety of “fascism,” an extreme outgrowth of capitalism, milder versions of which can be found in all capitalist societies, and “totalitarianism,” a form of radical authoritarianism characterizing both Nazi Germany and the Soviet Union. The second is between “intentionalists,” who see Nazi aggression and the destruction of the Jews as the result of a master plan, and “functionalists,” who see it as a sort of “industrial accident,” the conditions for which could be found almost anywhere but combined in unusual ways in Germany. Intentionalists emphasize both the evil machinations of leaders as well as unique desires inherent in German culture, while functionalists emphasize Germany’s delayed modernization, absent middle class, and polycratic (dis)organization. The social scientific and historical literatures thus range over a variety of causes and characteristics of the Nazi regime, including “massification,” secularism, nihilism, consumerism, militarism, imperialism, evolutionism, and modernity itself. In most such accounts, however, the dependent variable is National Socialism, not the Holocaust. Theories associating radical Nazi anti-Semitism and the Holocaust with modernity generally—such as Max Horkheimer and Theodor Adorno’s Dialectic of Enlightenment (written before the era of extermination camps, though it did not appear until 1944) and Zygmunt Bauman’s Modernity and the Holocaust (1989)—are perhaps the most successful because they seek to draw meaning rather than determine causation.

Beyond the more macrohistorical efforts to explain National Socialism (which, again, confound the Judeocide with political authoritarianism and militarism), a number of sociological and social-psychological studies have sought to confront the cruelty and evil of National Socialism and the extermination camps as general problems of deviant behavior and social psychology, thus
approaching the question equally as obliquely as the macrohistorical theorists. Adorno and colleagues conducted research into what they called “the Authoritarian Personality.” During the war the psychiatrist Richard Brickner diagnosed a collective paranoia, as did Jung after the war, both arguing for an occupation policy modeled on therapy for a neurotic patient. The sociologist Everett Hughes framed Nazi brutality as a matter of “good people and dirty work.” Similar to Hannah Arendt, who most famously described Nazi brutality as banal, not in the sense of being trivial but in the sense of being ordinary, the work of desk-chair perpetrators (Schreibtischtaeter), Hughes sought to understand the social processes that made ordinary people capable of extraordinary cruelty, just as theories of “differential association” and “socialization” explain other kinds of deviance. In a similar vein Christopher Browning’s studies of police officers who served in death squads underscore the universal capacity of every person for brutality in the right circumstances. Most famously the psychologist Stanley Milgram designed a series of experiments in which ordinary people were led, under a variety of conditions, to administer increasingly painful and finally lethal electrical charges to fictional test subjects, illustrating the general tendency for human beings to be “obedient to authority.”

Debates about the causes of National Socialism and of the centrality of the murder of the Jews are ongoing and frequently occasion public controversy. For instance, the political scientist Daniel Goldhagen’s 1996 book Hitler’s Willing Executioners attracted a great deal of public attention for its thesis that Germany exhibited a unique form of “eliminationist anti-Semitism” and that as a result ordinary Germans supported the extermination of the Jews. The consensus is that Goldhagen failed to establish the existence and operation of a uniquely “eliminationist” political culture. Goldhagen’s charge that macrohistorical and macrosociological accounts have not adequately conceptualized the centrality of Jew hatred has received less attention.

From about the 1980s on a particularly interesting strand of social scientific work focusing directly on the Holocaust developed concepts of “collective memory” and “cultural trauma” to understand the aftereffects of the Holocaust in contemporary culture. In the first place, collective memory scholars have studied how nations have confronted and commemorated both their victimhood and their complicity in the crimes. For Germany, the question has been what kind of an identity a nation held responsible for what many consider to be the worst crime in human history can have after such knowledge.

Elsewhere the questions have centered on the fluid boundaries between complicity and resistance; in Poland and Israel questions of the centrality of victimhood to contemporary identity have been key, and sociologists of memory have sought to understand the complex comparative dynamics of the different national cases. In the second place, theorists of trauma, both individual and cultural, have studied the problems of cultural and social transmission. For both survivors and perpetrators, scholars have identified unique legacies for the second and third generations, identifying both substantive problems from this particular history and general processes of intergenerational transmission. Finally, political sociologists have described the Holocaust as an interesting model for the “globalization” of memory, arguing that the cultural and ideological dimensions of the Holocaust and its implied indictment of modernity are diagnostic of the present condition and serve as a model for commemorative forms elsewhere as well as for the pursuit of redress claims in a variety of cases.

HOLY ROMAN EMPIRE

The foundation of the Holy Roman Empire is usually dated to the decision of Charlemagne (742–814), king of the Franks, to assume an imperial title on Christmas Day, 800. The exact reasons for this remain a matter of dispute, but were clearly related to Charlemagne’s personal mission to establish Christian rule in western and central Europe. The original empire was partitioned in 843, with the eastern portion retaining the association with the Christian imperial mission. This assumed greater ideological significance with the coronation of Otto I (r. 936–973) in Rome in 962 as he consciously invoked not only continuity with Charlemagne’s empire, but that of ancient Rome. The concept of “imperial translation” claimed that the empire was a direct continuation of that of ancient Rome in its final, Christian configuration, and so was the last of the four “world monarchies” prophesied in the Bible to rule over the earth before the Day of Judgment. Such ideas buttressed the emperor’s claim to be the supreme overlord of all other Christian rulers and thus the secular arm of a single, universal Christendom, leading to a prolonged dispute with the papacy.

The Christianizing mission combined with internal population growth to push the empire across the river Elbe early in the twelfth century, making it the largest polity in Europe until the growth of the Russian Empire in the eighteenth century. This expansion was assisted by the relative continuity of three successive imperial dynasties: the Ottonians (919–1024), the Salians (1024–1125), and the Staufers (1138–1254). However, the growth of more distinct kingdoms in western Europe restricted the emperor’s practical authority to the lands east of the Rhine and north of the Alps. Moreover, the emperor only ruled a small portion of the vast area directly, relying on a host of secular and spiritual lords, as well as autonomous cities to manage local and regional affairs. These lords (increasingly called “princes”) and cities evolved as the “imperial estates” (Reichstände) between the thirteenth and sixteenth centuries, each controlling a distinct territory within the empire, with their own subordinate clergy, nobility, towns, and rural communes.

The absence of a single imperial dynasty after 1254 assisted this process and led to an elective imperial title that became entrenched in Germany and could be assumed without papal participation. Following the demise of the Luxembourg dynasty (1347–1437), the title passed by election to the Habsburgs, who retained it with only a single break (1740–1745) until the end of the empire in 1806. The onset of prolonged warfare with France and the Ottomans coincided with the confessional strife of the Reformation, and social and economic change. These pressures forced constitutional change from the late fifteenth century, creating an elaborate web of written and customary rights intended to preserve the autonomy of the imperial estates and the corporate structure of central European society within a hierarchical political framework under the emperor’s overall authority, but not his direct rule. The growth of Austria and Prussia as distinct European great powers undermined this structure from within and led to its collapse during the Napoleonic Wars when the last emperor abdicated in 1806.

HOMELESSNESS

The National Law Center on Homelessness and Poverty indicates that, on any given day, approximately 840,000 people in the United States are homeless or living in temporary shelters. Approximately 3.5 million people in the United States will meet criteria for homelessness within a given year, and 1.35 million of them are children. It is estimated that 7.4 percent of U.S. residents, or as many as 13.5 million people in the United States, have been homeless at one point in their lives.

The majority of the homeless in urban areas are adult men of minority descent. In rural areas, however, the homeless are more likely to be Caucasian, and their genders and ages are less well known. Across both rural and urban settings, approximately 20 to 25 percent of the homeless adult population suffer from some type of severe and persistent mental illness. Although homelessness has been a historically significant phenomenon in the United States, it still remains difficult to cull reliable and comprehensive data about homeless individuals. Indeed given the difficulty of tracking and finding individuals who are homeless because of the variability in their locations,
national data may significantly underestimate the incidence and prevalence of this social condition.

In 1987 the Stewart B. McKinney Homeless Assistance Act marked the first time the U.S. government acknowledged homelessness as a national crisis, despite its prevalence for decades prior to this event. In addition to designating federal money to help research and solve the problem of homelessness, the McKinney Act also provided a clear definition of homelessness. According to the legislation, a "homeless" individual is one who lacks a fixed, regular, and adequate nighttime residence or has a primary nighttime residence that is a supervised publicly or privately operated shelter, an institution that provides temporary residence for individuals who will be institutionalized, or a public or private place not ordinarily used as regular sleeping accommodations for human beings.

The term homeless is inapplicable to individuals who are imprisoned or detained under congressional or state law. The concept as understood in the United States is largely based on an individual's physical living arrangements or accommodations. However, as the literature suggests, this definition may be inadequate and unable to capture the complexity of phenomena internationally. Indeed this U.S. definition of homelessness reduces the concept to an issue of "houselessness," which is a critical caveat to achieving an international understanding of the phenomenon.

The United Nations Centre for Human Settlements (Habitat) has refined homelessness and developed a more globally appropriate and responsive definition. The center also recognizes that definitions of homelessness vary widely and are influenced by geographic and socioeconomic factors. Most of what is known about homelessness, including an accepted definition of the construct, is based on the limited statistics and information available from European and North American countries and from the developing country of India. From this perspective, commonly held conceptualizations of homelessness include a consideration of social and familial relationships and sociodemographic factors.

Globally it is estimated that between 100 million and one billion individuals are homeless. Notably, however, homelessness data from developing countries are particularly sparse and difficult to collect. Across developed and developing countries, homelessness is often understood through both the narrow lens of accommodations, or lack thereof, and broader perspectives in an effort to inform services and interventions for those affected. For example, while some countries employ a typology based on characteristics of housing quality or on the length of time an individual is homeless, other countries may use a typology based on risk or potential of facing houseless conditions.

There are some emerging cross-cultural categories for understanding homelessness in an international arena. For example, supplementation homelessness, whereby an individual is homeless in response to migration, is quite different from survival homelessness, whereby individuals are homeless because they are searching for improved opportunities. Crisis homelessness, a precipitant of homelessness produced by a crisis (such as a storm, earthquake, or war) is quite different from the previous two. These categories focus more on the etiology for homelessness rather than on factors directly associated with the homeless individuals' culture, race, or premorbid socioeconomic status.

From a global perspective, much attention is given to homeless children and adolescents, often referred to as street children. It was estimated that there were 100 million street children worldwide in 1992, with 71 million of these children working and living on the streets full-time, 23 million working and living on the streets part-time, and approximately 7 to 8 million abandoned. While street children are considered among the homeless, the literature makes clear distinctions between homeless adults and homeless children. The most accepted definition of a street child is "any girl or boy for whom the street (in the widest sense of the word, including unoccupied dwellings, wasteland, etc.) has become his or her habitual abode and/or source of livelihood; and who is inadequately protected, supervised, or directed by responsible adults" (Glasser 1994, p. 54).

Such a definition addresses characteristics in addition to physical living arrangements with a broader consideration of a child's basic needs (that is, need for security and socialization). Similar to the various typologies used to understand global homelessness among adults, a typology has been developed by UNICEF that differentiates street children who live at home and those who do not, which is particularly relevant given that the majority of street children have some contact with their families.

Specifically the literature has found that there are experiential differences between street children who are deemed at high risk of homelessness (that is, the child spends some time in the streets), street children who are in the streets (for example, they spend most of their time in the streets, usually working), and street children who are of the streets (that is, the street is the child's home). As with the typologies used with homeless adults, these categories may be useful in determining the level and the type of services needed.

Homelessness is an international crisis. The understanding of who is most affected and under what conditions as well as the ability to programmatically remediate the social ills that promote this condition are further limited by the national definitions that are often internally valid but not well generalized internationally.

HOOVER, J. EDGAR
1895–1972

John Edgar Hoover was born in Washington, D.C., on January 1, 1895, and died there on May 2, 1972. He served as director of the U.S. Bureau of Investigation (BOI)—known after 1935 as the Federal Bureau of Investigation (FBI)—from 1924 until his death. During his long tenure he greatly expanded the bureau, giving to it much of its modern identity, but he was also the focus of a great deal of controversy because of his autocratic leadership style and his frequent abuses of power in the name of fighting subversion.

After earning a law degree from George Washington University in 1917, Hoover joined the Justice Department during World War I (1914–1918), working in (and briefly heading) its Enemy Aliens Registration Section. Two years later he was chosen as head of the newly established General Intelligence Division of the Justice Department. In this capacity, he was involved in the Palmer Raids (1919–1920), during the course of
which U.S. Attorney General A. Mitchell Palmer (1872–1936) ordered the arrest of thousands of radical political figures, violating their civil rights, and deporting hundreds who were not U.S. citizens. Hoover’s role in this effort eventually led to his appointment by President Calvin Coolidge as the sixth director of the Bureau of Investigation in May of 1924.

As director of the BOI, Hoover expanded the bureau’s staff. He also modernized its methods of conducting criminal investigations by, among other things, establishing what would become the FBI Laboratory and amassing, in the bureau’s Identification Division, an enormous collection of criminal’s fingerprints. The bureau rose to prominence during what is often referred to as the “lawless decade” of the 1920s, and during the 1930s it engaged in a number of high-profile battles with such famous criminals of the Depression era as John Dillinger, Alvin Karpis, Bonny Parker and Clyde Barrow, and Machine Gun Kelly. After its name change to the Federal Bureau of Investigation in 1935, the bureau became increasingly a part of the American vocabulary.

During World War II (1939–1945) the bureau played an important role in domestic surveillance, and its efforts led to the capture of a number of Nazi agents and saboteurs working undercover in the United States. In the years following the war, however, Hoover’s war against subversion took a more controversial turn. During the late 1940s and early 1950s he became deeply involved in the anti-Communist movement known popularly as McCarthyism—after the reckless, witch hunt methods of Senator Joseph McCarthy of Wisconsin (1908–1957). In the name of rooting out Communist subversion, Hoover authorized illegal wiretapping and spying on thousands of suspected Communists. In the second half of the 1950s he expanded his area of concern to the emerging civil rights movement, which he also believed to be subversive in character. He sought to discredit the work of the early civil rights leader T. R. M. Howard (1908–1976), and later made similar efforts against Martin Luther King Jr.

Hoover served during the administrations of eight presidents, and while several of these individuals—especially Truman, Kennedy, Johnson, and Nixon—felt that he had grown too powerful, none was able or willing to remove him from office, due in part to his and the FBI’s near-iconic status in the mind of the average American. Celebrations of the FBI in American popular culture that contributed to this status included a long-running radio program (The FBI in Peace and War, 1944–1958), a popular television series (The F.B.I., 1965–1974), and a 1959 film, The FBI Story, starring the well-known Hollywood actor James Stewart. Hoover himself was the author of several books, among them the best-selling Masters of Deceit: The Story of Communism in America and How to Fight It (1958).

Hoover’s management style at the bureau was highly autocratic, and he was greatly feared by those who worked for him. Following his death in 1972, Clyde Tolson (1900–1975), his longtime friend and associate FBI director, succeeded him as director.

In the years following Hoover’s death the controversies surrounding his life and career have continued to grow. Among them, suggestions of homosexuality (in Anthony Summers’s Official and Confidential: The Secret Life of J. Edgar Hoover [1993]) and possible African American ancestry (in Millie McGhee’s Secrets Uncovered: J. Edgar Hoover—Passing for White? [2000]) have rendered particularly ironic Hoover’s use of information regarding sexual orientation as a means of attacking or intimidating political opponents and his strong opposition to the post-war civil rights movement.

HOPE

In an ancient Greek myth, Zeus was irate at humans for having stolen fire from the gods. In the spirit of revenge, he fashioned a young maiden named Pandora and, using reverse psychology, sent her to earth with a dowry chest, with the crucial instruction not to open it. Of course, her curiosity got the best of her, and she opened the lid. Out came a plague of evil forces. Panicked at what she had unleashed, Pandora tried to close the chest, only to find that hope was stuck on the lid. Hope could overcome the evil forces unleashed. Thus hope came into the world.
A young couple stood at the graveside of their two twin daughters, born prematurely, as a circle of family and friends sang the hymn, “Lead, Kindly Light, Amid the Encircling Gloom.” Having their precious daughters buried near their great grandparents in a historic cemetery brought them comfort and hope in the face of perinatal loss (Callister 2006). Hopefulness in such situations is a personal, comforting, and life-sustaining belief that even in difficult times, life has meaning. Hope is also a belief that something favorable can happen for oneself or others in the future. P. S. Hinds (1984) defined hope as the human characteristic that allows an individual, irrespective of age, to transcend disappointments, pursue goals, and diminish the sense of the future as unbearable or futile. Hope is a force contributing to a person's will to live (Cousins 1989).

Detractors to hope exist. It is postulated that inside every person there is a spirit of hopefulness that can be influenced negatively or positively by others. Suffering and feeling alone or unappreciated, along with unaddressed spiritual needs, are some of the challenges to being hopeful.

James Averill and his associates (1990) asked people to describe circumstances in which they thought hope would be important. Responders described periods when they perceived some degree of personal control over their lives, and times when their life goals were important, had a reasonable chance of being reached, and were socially and morally acceptable.

Strategies that contribute to the strengthening of hope include believing in oneself, trusting in the good intentions of others, and feeling close to another person. For many people, faith and religious beliefs also contribute to hopefulness. Hope is vital for those who have been diagnosed with a serious, life-threatening, or terminal illness, as well as for their families. Those who lack hope find no meaning in life or find it difficult to persevere in troubling times. They may lack or lose a sense of well-being, and doubt the possibility of favorable outcomes. The components of hope include “positive thinking or optimism, reality-based and future oriented goals, positive future for self or others, and positive support systems” (Hendricks-Ferguson 1997, p. 76). Hope is essential to negotiating difficult life challenges. Knowing that others have hope for positive outcomes can foster hope in individuals.

On the other hand, hope may be perceived by others as evidence that individuals and families are unrealistically positive. Thus, hope may become simply “magic” when one has a wishful expectation that everything will “turn out all right” based on luck, fate, or the intervention of a higher power. Still, hope can be fostered by reflecting on positive outcomes and by formulating potential goals. Hope thus becomes realistic as one recognizes the existence of limitations or conditions.

Multiple tools have been developed to measure hope, including the adult hope scale developed by C. R. Snyder and colleagues (1991). Eight items are ranked on an eight-point Likert scale from “definitely false” to “definitely true,” with four agency items such as “I energetically pursue my goals.” The higher the score, the higher the level of overall hope. A similar children's hope scale has also been developed.

Hope has been studied across the lifespan. Kaye Herth (1998) used interviews and drawings to study sixty homeless children who had lived through multiple losses. Themes included connectedness, internal resources, cognitive strategies, energy, and hope objects. The children used symbols in their drawings, most often trees or rainbows, which for them symbolized hope. As one homeless adolescent wrote, “a young tree is very fragile and in need of just the right amount of water and sunlight to grow; hope at first is very fragile but flourishes with care” (Herth 1998, p. 1057). Many of the children drew pictures of houses, with open doorways and flowers and favorite toys, indicating a longing to have a “real home.” One child who drew a sad face explained, “sometimes you have to be sad before you can smile again” (Herth 1998, p. 1058). The adolescents shared stories of significant losses but demonstrated inner strength that sustained their hope. One favorite book at the shelter was The Little Engine that Could, with the hopeful refrain, “I think I can, I think I can.”

Adela Yarcheski and associates (1994) studied ninety-nine high school students, finding statistically significant positive correlations between perceived hopefulness and social support, as well as hopefulness and general well-being. Hopefulness was fostered through social interaction, mutuality, attachment, intimacy, affirmation, encouragement, and a nurturing environment. Hopefulness in adolescents with cancer has also been studied and has been linked with improved quality of life and better health even in the face of chronic or terminal illnesses (Hendricks-Ferguson 1997).

Hope is experienced differently by those who are chronically ill than by those who are healthy. Dal Sook Kim and associates (2006) studied hope in chronically ill hospitalized patients and identified five life orientations related to hope:

- Externalism orientation—hope based on reliance on family, friends, or God.
- Pragmatic orientation—hope in the ability to accomplish small things in life.
- Reality orientation—hope manifested by realistically enjoying that which can be.
• Future orientation—hope focused on positive possibilities that may exist in the future, which may include a strong reliance on a higher power; for example, a person may say, “I feel hope in my faith in God” or “I feel hope when I realize that I am in God’s hands.”

• Internal orientation—hope oriented toward the self.

J. M. Morse and B. Doberneck (1995) studied patterns of hope exhibited in a variety of people undergoing different life experiences. Their subjects included breast cancer survivors, individuals waiting for heart transplants, unemployed mothers, and persons with spinal cord injuries. The presence and function of hope has also been studied in people with acute spinal cord injuries (Lohne and Severinsson 2004) and adults undergoing bone marrow transplants for leukemia (Ersek 1992). In Mary Ersek’s study, factors associated with hope included “feelings of powerfulness or control, meaning or purpose in life, adequate social support, and positive self esteem” (1992, p. 883). Ersek identified the structure of hopefulness as:

- Appraising the illness in a nonthreatening manner (seeing it as a positive event).
- Cognitively managing the illness experience (including the practice of joking).
- Managing emotional responses to the illness.
- Managing a sense of control (either maintaining or relinquishing control).
- Taking a stance toward illness and treatment (fighting the illness or accepting it).
- Managing the uncertainty (minimizing or maximizing the uncertainty).
- Focusing on the future (living from day to day or focusing on the long term).
- Viewing the self in relation to the illness (minimizing the illness and maximizing personal strengths).

Further research is needed to increase our understanding of hope, including how to mediate the variables and strategies that enhance hope in individuals across the lifespan. Many experts assume that sources of hope include support from family and significant others, as well as spiritual beliefs (Hendricks-Ferguson 1997). How these sources of hope make a difference merits further inquiry.

HOT MONEY

Hot money may be defined in two ways. Currency traders define it as opportunistic funds seeking the highest short-term return in international markets, moving from one trend to the next—hence, its highly liquid or “hot” character. In more journalistic usage, the adjective refers to money whose ownership is concealed at least from the tax authorities and often from criminal prosecutors as well. This is done by creating corporate shells, and it is done increasingly legally, blurring the boundary between legal and illicit. Rather than countering the activity, European and American governments have promoted it and offered special tax advantages in order to attract this money.

The corrupt associations of “hot money” derive less from the activity itself than from the social status of its practitioners. It is disparaged when the funds come from dope dealing and arms trading or from small-fry falsifying their tax returns. But hot money is blessed and even given special tax subsidy when conducted at the top of the economic pyramid.

Early hot-money centers were Switzerland, Liberia, and Panama. Switzerland long refused to cooperate with foreign criminal prosecutors on the logic that its laws did not recognize tax avoidance as a crime. Liberia and Panama offered “flags of convenience” to the oil industry and refrained from imposing any income or sales taxes in a fiscal “race to the bottom.” Oil companies avoided taxes by incorporating shipping affiliates in Panama and Liberia to buy crude oil at low prices from their branches in the producing nations and sell them at a high enough markup to their refineries in the consuming nations, so that neither oil wells nor refineries had reportable income.

By the 1960s these tax-avoidance centers inspired smaller versions throughout the Caribbean and other islands. These “offshore banking centers” specialized in legal “tax avoidance” as distinct from outright tax evasion. By far the major quantitative suppliers of funds in such centers are large multinational corporations, global money managers, and post-Soviet kleptocrats. Smaller fry simply have moved in their wake, facilitated by the international banks that have set up branches in these enclaves.

When the U.S. dollar came under pressure in the late 1960s, Congress voted to refrain from imposing the usual 15 percent income-tax withholding on interest paid to holders of Treasury bonds in these centers. Deeming it to be in the U.S. interest to attract tax-evasion money and the soaring sums of overtly criminal wealth to stabilize the balance of payments, the government encouraged U.S. banks to set up branches in these centers. Britain announced a similar rationale to permit its residents to conduct real estate and other transactions via the Channel Islands, along with the British West Indies and a few other imperial dependencies in the Caribbean. For continental Europe, Liechtenstein and more recently Cyprus have played a similar role, with Russian oligarchs and their counterparts in other parts of the former USSR favoring Cyprus.

The prize for banks in these centers is a volume of flight capital, tax-avoidance, and criminal money that took a quantum leap after the breakup of the Soviet Union in 1991. Capital flight from Russia alone is estimated at $25 billion annually since that time. Usually a “veil of tiers” is set up by lawyers using multiple offshore banking centers to make the funds more difficult to trace. The ultimate magnitude is reported regularly by central banks. The Federal Reserve Board reports U.S. deposits from offshore banking centers quarterly, segregating out deposits at U.S. bank branches. The Bank of England and the German Bundesbank publish similar quarterly reports in their central bank bulletins, and U.S. congressional committees periodically hold hearings to assess how the rising flow of hot money can best be tapped to serve U.S. national interests.

These statistics show the major role hot money has come to play in international banking. The United States has become the world’s largest hot-money haven, followed by Britain. The Bank of Credit and Commerce International and Riggs Bank in Washington, D.C., and the Bank of New York and Citibank have been singled out for serving kleptocrats, dictators, and smaller crooks, highlighted by the uncovering in 2004 of secret accounts for former Chilean dictator Augusto Pinochet (1915–2006). An eight-year 1998–2006 FBI probe of money laundering focused on operations by Semion Mogilevich and other members of Russia’s mafiya at the Bank of New York.

In sum, the growth of “legitimate” savings by multinational firms, government officials, and major vested interests makes any estimate of the magnitude of hot money fairly irrelevant. Different observers may draw the line at different points along the line from respected multinationals to small-time tax dodgers and crooks who use these centers to make their money invisible to the tax and police authorities.

HOUSTON, CHARLES HAMILTON
1895–1950

Charles Hamilton Houston was born in 1895, one year before the U.S. Supreme Court’s decision in Plessy v. Ferguson. In Plessy, the Court upheld laws requiring racially segregated public facilities, known as Jim Crow laws, ruling that “separate but equal” facilities for blacks and whites did not violate the U.S. Constitution. Charles Houston dedicated his life to destroying Jim Crow and ending racial segregation by law in the United States.

Houston believed that the law could be used to bring about social change and that black lawyers should be trained as social engineers. He attended law school at Harvard University, where he was the first black editor of the Harvard Law Review. In 1929 Houston was appointed head of the law school at Howard University, a historically black institution. Houston raised admissions standards, improved the faculty, strengthened the curriculum, and achieved accreditation for the school. His mission was to train a cadre of black lawyers that would successfully challenge government-sanctioned discrimination. One of Houston’s students, Thurgood Marshall (1908–1993), went on to argue Brown v. Board of Education (1954) before the U.S. Supreme Court and later to serve as the Court’s first black justice.

In 1935 Houston took a leave of absence from the law school to serve as special counsel to the National Association for the Advancement of Colored People (NAACP). Within a few months of joining the NAACP, Houston initiated a legal campaign to end racial discrimination in public education. The first step in Houston’s strategy was to attack Plessy’s “separate but equal” doctrine as it applied to graduate and professional schools. Most states offered legal education only to white students, thus failing to meet the “separate” requirement, and Houston brought test cases to challenge these policies. In Murray v. Maryland (1936) and Missouri ex. rel. Gaines v. Canada (1938), the Maryland Court of Appeals and the U.S. Supreme Court ruled that states must either admit black students to their established institutions or provide blacks with equal facilities for graduate and professional training.

Houston resigned as NAACP special counsel in 1938, but he remained active in civil rights litigation. He turned his attention to racial discrimination in labor and housing. In the Steele and Tunstall cases of 1944, Houston successfully challenged preferential hiring in the railroad industry, and in Hard v. Hodge (1948), he took on restrictive covenants among homeowners and prevailed.

Houston also continued to advise Thurgood Marshall, who had taken over the education litigation. The next step was to challenge the separate graduate and professional schools created in the wake of Murray and Gaines and to show that equality was impossible, or at least too expensive, to achieve. In Sweatt v. Painter (1950) and McLaurin v. Oklahoma (1950), the NAACP argued that the education offered to black law and graduate students was substantially inferior to that available to white students, and the Supreme Court unanimously agreed.

Houston died of heart failure in 1950 and did not live to see the culmination of his strategy to overturn Plessy v. Ferguson. In Brown v. Board of Education (1954) and its companion cases, the Supreme Court was unanimous in striking down segregation in primary and secondary education, declaring that “in the field of public education the doctrine of ‘separate but equal’ has no place.”

HULL, CLARK
1884–1952

A leading American psychologist during the middle decades of the twentieth century, Clark Leonard Hull established an early reputation for carefully controlled research and formulated an influential version of neobehaviorist learning theory. His ambitious theoretical system was marked by quantitative precision and systematic exposition in terms of postulates and equations.

Hull was raised on a small farm in Michigan and attended Alma College in preparation for a career in engineering. But while convalescing from polio, he read
William James’s *Principles of Psychology* (1890) and transferred to the University of Michigan to study psychology. He then entered graduate school at the University of Wisconsin, receiving a doctorate in 1918 with a thesis on concept formation under the direction of Joseph Jastrow (1863–1944).

Remaining at Wisconsin as an instructor, Hull pursued research in three areas. His study “The Influence of Tobacco Smoking on Mental and Motor Efficiency” (1924) produced mixed results but was noteworthy for implementing a placebo design in which blindfolded subjects smoked pipes that delivered either tobacco or heated, smoke-scented air. He also conducted quantitative studies of aptitude testing and carefully controlled research on hypnosis, eventually publishing well-received books on both topics. His *Hypnosis and Suggestibility* (1933) was a pioneering work in the scientific study of hypnotic phenomena.

In 1929 Hull received an appointment at Yale, where his interests shifted to behaviorist learning theory. Inspired by the works of the Russian physiologist Ivan Pavlov (1849–1936) and the American psychologist Edward Thorndike (1874–1949), he published a series of “miniature systems”—theoretical models of limited scope that applied to circumscribed domains of learned behavior. The systems made ingenious use of the explanatory constructs—such as pure stimulus acts and habit-family hierarchies—that would become standard devices for “Hullians” in the following decades. During the 1930s, Hull also designed and built robotic machines that could exhibit learned behavior, a practice that prefigured later uses of computers to model mental processes.

Meanwhile, Hull assumed a leadership role at Yale’s Institute of Human Relations, which attracted talented young psychologists otherwise unemployed during the Great Depression. Hull’s weekly seminars at the institute were devoted to applications of behavioral principles to phenomena of social learning, aggression, and psychopathology. His students and associates at Yale included such notables as Neal Miller, John Dollard, Eleanor Gibson, Charles Osgood, Robert Sears, and Kenneth Spence. As Hull’s chief disciple, Spence trained scores of students in the Hullian tradition at the University of Iowa.

Elected president of the American Psychological Association in 1936, Hull furthered his standing with the 1943 publication of his masterwork *Principles of Behavior*. Consistent with the logical positivist philosophy of the time, the book adopted a hypothetico-deductive method in which theory was framed as postulates and theorems to be subjected to experimental verification. It quickly became the most cited work in experimental psychology and led to Hull’s involvement in celebrated learning-theory debates, notably with Edward Tolman (1886–1959) and Kurt Lewin (1890–1947), during the 1940s.

In *Essentials of Behavior* (1951), Hull revised the postulates of the *Principles* in light of anomalous findings, but his system became mired in the complexities of learned behavior. By the late 1960s, his influence had crested and many psychologists were turning to the simplified neobehaviorism of B. F. Skinner (1904–1990) or to cognitive approaches. Hull’s efforts at grand theory are now largely regarded as failures, but his legacy of careful experimentation and domain-limited theoretical models remains influential.

**HUMAN CAPITAL**

According to marginal analysis, each factor of production is paid according to its contribution to production, and the market constitutes a mechanism that establishes a moral rule of distributive justice in the society. This theory of marginal productivity was put forth around the turn of the twentieth century by the American economist John Bates Clark (1847–1938). In the neoclassical analysis of the labor market, the equilibrium wage is set at the point of intersection of the demand and supply curves of labor. The level of the equilibrium wage set by the intersection of the two curves guides the allocation of workers across firms in such a way that an efficient allocation of resources is achieved. The implication is that wages are equal to the value of the marginal product of labor, which is the same for all workers and every firm. To achieve this condition, firms and workers should operate in a perfectly competitive environment, anonymity for both sides should be present, and the allocation of labor to firms should be random. However, wage differentials are present in the labor market, and several attempts have been made to explain the reasons for these wage differentials.

Adam Smith (1723–1790) was the first economist to introduce the idea of wage differentials and attempt to
offer reasons for its existence. According to Smith, one reason for wage differentials is the common idea that wages vary positively, everything else being held constant, with the disutility of labor. This argument was later formalized by William Stanley Jevons (1835–1882) and states that an individual is willing to offer more labor input only if the wage is higher; this is because leisure time gets scarcer and thus becomes more valuable to an individual. Another reason for relative wage differentials put forward by Smith is related to the concept of human capital, which has been introduced only recently into economic analysis. According to Smith, the cost of a person’s education or training can be viewed as an investment in the individual’s future earnings capacity, analogous to an investment in physical capital. To be economically justified, this investment must be recuperated over the lifetime of the student or trainee. Thus, those with education or training will generally earn more than those without. In recent years, this interpretation of wage differentials has given rise to numerous attempts to measure the rate of return on investment in education and training. In general, these efforts have sought to check whether such investments in education and training do, in fact, earn normal profits for an equally valuable capital.

Neoclassical theory has never abandoned the idea that wages tend to equal the net product of labor; in other words, the marginal productivity of labor rules the determination of wages. However, it has also been recognized that wages tend to retain an intricate, although indirect, relationship with the cost of rearing, training, and sustaining the energy of efficient labor. All these factors cause wage differentials, and they make up what is known as human capital in economic literature. Human capital, in mainstream economics, is similar to the physical means of production—for example, factories and machines—and is defined as the knowledge and skills possessed by the workforce that can be accumulated. Human capital, therefore, is a stock of assets that one owns and that allows one to receive a flow of income, similar to interest earned. In modern times, human capital is largely a product of education, training, and experience. Within this approach, investment in human capital is treated similarly to investment in physical capital and is considered, in many cases, as a principal factor for the observed differences in developmental levels between nations. It is argued that investment in human capital can take various forms, including improvements in health services, formal education, and training of employees, and it can help eliminate blockages in productivity enhancements. It is worth clarifying that the acquisition of more human capital is not related to the number in the workforce but to the improvement of labor services and the concomitant increase in labor productivity.

Today, new growth theorists put a lot of emphasis on human capital: “The main engine of growth is the accumulation of human capital—or knowledge—and the main source of differences in living standards among nations is a difference in human capital. Physical capital plays an essential but decidedly subsidiary role. Human capital takes place in schools, in research organizations, and in the course of producing goods and engaging in trade” (Lucas 1993, p. 270). Within this framework, a lot of emphasis is given to the policies promoting human capital, such as investment in education or health. More than that, according to the economists Theodore W. Schultz (1902–1998) and Anthony P. Thirlwall, it is argued that differences in the quality of human capital are the cause of the different levels of development among nations and that the improvement of human capital might reduce the need for physical capital.

In addition, literature about organizational behavior and human resource management has emphasized the role of human capital in promoting the development and implementation of national and corporate strategies. Hence, human capital is a very important asset and may serve as a useful link in the chain between employee and business performance; moreover, human capital, human-resource practices, and firm performance are areas that need to be explored together to design better corporate strategies.

**MINCER’S WAGE EQUATIONS**

Modern human capital theory was initiated by the work of Jacob Mincer, in which investment in human resources is considered similarly to other types of investments. In Mincer’s first model (1958), individuals are assumed to be identical prior to any training, thereby forcing a differential wage to employment based on the length of the expected training period. The size of the compensating differential is determined by equating the present value of the future net earnings stream (gross earnings minus costs) with the different levels of investment. The formal presentation of Mincer’s first simple model is:

\[
\ln w(s) = \ln w(0) + rs
\]

where \( \ln w(s) \) represents the log of the annual earnings of an individual with \( s \) years of education, \( \ln w(0) \) represents the log of the annual earnings of an individual with basic years of education, and \( r \) is the internal rate of return to schooling years \( s \). According to the above equation, individuals with more training receive higher earnings. The difference between earning levels of individuals with different years of schooling is determined by the second term of the right-hand side of the equation. If one defines the internal rate of return to schooling as the discount rate that equates the lifetime earnings stream for different educational choices, then the internal rate of return to schooling can be estimated by the coefficient on years of
schooling. This simple framework offers a number of interesting implications. However, the whole analysis relies on some unrealistic assumptions, which can be summarized as follows:

- the individuals are all identical prior to making choices;
- the age of retirement does not depend on years of schooling;
- the only cost of schooling is foregone earnings;
- earnings do not vary over the life cycle; and
- there is no post-school on-the-job investment.

Mincer's second model (1974) allows for the on-the-job investment and yields an earnings specification that is similar to the first. To establish the relationship between potential earnings and years of labor-market experience, assuming that observed earnings are equal to potential earnings less investment cost, the following relationship for observed earnings is produced:

$$\ln w_s(x) = a_0 + \rho s + \beta_0 x + \beta_1 x^2$$

where $\ln w_s(x)$ stands for the observed earnings, $x$ is the amount of work experience, $\rho$ is the rate of return on formal schooling, and $s$ represents the years of education. The intercept term is the product of the log skill price and the initial ability of the individual. The coefficients $\beta_0$ and $\beta_1$ stand for the return to experience.

This second expression is called Mincer's standard wage equation, which regresses the log earnings on a constant term, on a linear term of the years of schooling, and on a quadratic term of the labor-market experience. Mincer's standard wage equation transforms a normal distribution of years of schooling into a log-normal distribution of earnings. Under the assumption that post-school investment patterns are identical across individuals and do not depend on the schooling level, Mincer shows that there is an important distinction between age-earnings profiles and experience-earnings profiles, where experience means years since leaving school. More specifically, he shows that the log-earnings-experience profiles are parallel across schooling levels and that log-earnings-age profiles diverge with age across schooling levels.

By the early 1970s, the estimation of the returns on schooling using Mincerian wage regressions had become one of the most widely analyzed topics in applied econometrics. The reason is that the human-capital earning function has several distinct characteristics that make it particularly attractive:

- the functional form is not arbitrary, and the identity is based on the optimizing behavior of individuals as captured by the outcome of the labor-market process;
- it converts immeasurables (the dollar cost of investment in human capital) into measurables (years of schooling and years of labor-market experience);
- it can include instrumental variables to capture a dichotomous variable describing some characteristics such as race or sex; and
- the coefficients of the regression equation may be attributed with economic interpretations.

While the human-capital literature has now been generalized to incorporate on-the-job training, it should be noted that the Mincerian wage regression equation is a representation of the statistical relationship between wages and experience (given schooling) for an exogenously determined rate of on-the-job training. The Mincerian wage regression disregards the endogeneity of post-schooling human-capital accumulation and treats schooling and training symmetrically. More precisely, Mincer's approach ignores the possibility that schooling may change the human-capital accumulation process that takes place on the job.

THUROW'S JOB-COMPETITION MODEL

C. Lester Thurow’s job-competition model serves as an interesting counterpoint to the traditional models in explaining the distribution of earnings. In his book *Generating Inequality: Mechanisms of Distribution in the U.S. Economy* (1975), Thurow shows that for the period 1950–1970, changes in the educational attainments of white males 25 to 64 years old did not affect their earnings. He finds that educational distribution is equalized through the years while income distribution is not, and he notes that the expected arguments and results from marginal productivity are not fulfilled. To explain the distribution of wage earnings, Thurow rejects market imperfections as a possible explanation of unexpected observations in labor markets. In fact, he argues that individuals compete against one another for job opportunities based on their relative costs of being trained to fill a job position instead of based on wages they are willing to accept. He argues that wages are based on the marginal productivity of the job, not of the worker. Workers who compete for jobs offered at fixed wages determine the labor supply, and workers compete for relative positions based upon their training costs to employers rather than on wages. Hence, job competition prompts people to overinvest in formal education for purely defensive reasons. Moreover, technology, the sociology of wage deter-
mination, and the distribution of training costs determine the distribution of job opportunities.

Even though the advantages of education are frequently exaggerated in terms of their strictly economic results, there is no doubt that education is advantageous in earning a higher income and also teaches general skills that improve the quality of labor and, by extension, human capital. However, recent literature on issues related to human capital stresses the need to consider other dimensions of human identity that contribute to the formation of human capital. In fact, modern labor economics has criticized the simple approach that tries to explain all differences in wages and salaries in terms of human capital as a function of knowledge, skills, and education. The reason is that the concept of human capital can be infinitely elastic, including unmeasurable variables such as culture, personal character, or family ties. Many other factors, therefore, may contribute to wage differentials, such as gender or race. The existence of imperfections in labor markets implies the existence of segmentation in labor that causes the return on human capital to differ between different labor-market segments. Similarly, discrimination against minority or female employees implies different rates of return on human capital. Most of these studies in their wage equations use the technique of instrumental (or dummy) variables to introduce specific characteristics of the labor segmentation that takes place. The statistical significance of these instrumental variables indicates their importance in forming human capital and the concomitant wage differentials. In addition, over the past few decades several writers, including Rhonda Williams (1991) and Howard Botwinick (1993), have begun to develop alternative approaches to the analysis of discrimination and wage differentials that are based on a more classical analysis of capitalist competition and accumulation.

**HUMAN CAPITAL AND RELATED FIELDS**

The theoretical discussion about the meaning of human capital is vast and extends into the fields of human development and human resource management. For instance, human-development literature often distinguishes between specific and general human capital, where the first refers to specific skills or knowledge that is useful only to a single employer, while the second refers to general skills, such as literacy, that are useful to all employers. Human-development theories also differentiate social trust (social capital), sharable knowledge (instructional capital), and individual leadership and creativity (individual capital) as three distinct forms of human participation in economic activity.

Indisputably, the term human capital is used everywhere in economic and business analysis in which labor has to count as an input in the production process. The term has gradually replaced terms such as laborer, labor force, and labor power in the relevant analysis, giving an impression that these traditional terms are socially degraded. Moreover, in the strict sense of the term, human capital is not really capital at all. The term was originally used as an illustrative analogy between, on the one hand, investing resources to increase the stock of ordinary physical capital (such as tools, machines, or buildings) in order to increase the productivity of labor and, on the other hand, investing in educating or training the labor force as an alternative way of accomplishing the same general economic objective. In both sorts of investment, investors incur costs in the present with the expectation of deriving future benefits over time. However, the analogy between human capital and physical capital breaks down in one important and very crucial respect. Property rights over ordinary physical capital are readily transferable by sale, whereas human capital itself cannot be directly bought and sold on the market. Human capital is inseparably embedded in the nervous system of a specific individual and thus it cannot be separately owned. Hence, at least in regimes that ban slavery and indentured servitude, the analogy between human capital and physical capital breaks down.

HUMAN ECOLOGY

Human ecology, the study of the relationships between humans and their environments, is a field with a large scope and complex history. It arose out of multiple disciplines—animal biology, anthropology, geology, ecology, and sociology—in the early 1900s as scientists struggled to make sense of the impact of humans on the man-made and natural environment and the impact of environments on the social systems of humans. Human ecology is also viewed by many as a methodology or framework for studying human activities and social institutions, often in conjunction with the health and functioning of the natural environment.

HISTORY AND DEVELOPMENT

The earliest mention of human ecology can be found in the early 1900s among animal ecologists, who, as a result of studying population trends among plants and animals, suggested that ecological principles also applied to humans and their relationship to the natural environment. Later, biological ecologists and population scientists used similar concepts—such as ecosystem, environmental niche (the space occupied by an organism in which it can survive and reproduce), feedback loop, stability, and growth—to address issues of population growth and environmental destruction; this line of study became particularly prominent in the 1960s and 1970s, as in the 1973 work of Paul Ehrlisch, Anne Ehrlisch, and John Holdren. Also in the 1970s, Urie Bronfenbrenner (1979) developed an ecological model of human development to understand the reciprocal relationships between individuals and the multiple environments in which they live. Gerald Marten (2001) uses human ecology and complex systems theory as a framework to examine economic systems and other social institutions and their impact on the natural environment. In particular, he discusses human ecology as a tool for resolving issues of sustainable development and environmental problems by understanding the complex interrelationship between human social systems and the ecosystem.

Anthropologists used ecological concepts to study the history and culture of human groups and societies to explain their success, failure, or adaptation. The concepts of equilibrium, movement of resources, sustainable development (meeting present needs without compromising the ability of future generations to meet their own needs), and the adaptation of organizational systems have been applied to the study of families, communities, race relations, schools, workplaces, government agencies, and other social institutions. It was in the study of urban environments that the concepts of human ecology achieved prominence. Sociologists working in this area—Park and Burgess (1920s), Frazier and Sutherland (1930s), and Janowitz (1950s)—addressed key issues such as the impact of human settlement on land-use patterns (for example, traffic flow patterns, water and flood management), the intertwined history of industrial development and urban decay, race relations, and white flight to the suburbs—in other words, the components of urban and regional planning. The underlying issue is understanding how demands for space and resources influence the development of community and business organizations across rural and urban landscapes, and how the environment influences the structures and strictures imposed by human social systems.

The sociological approach to human ecology was epitomized by the Chicago School—an approach to research pioneered most famously by the Department of Sociology at the University of Chicago beginning in the 1920s and 1930s—which focused on using theory and field research methods to understand human behavior and organization in the urban environment. Beginning in the early 1920s, scholars such as Ernest Burgess and Robert E. Park employed ecological concepts to explain the development of cities and communities. For example, the POET model—population, organization, environment, and technology—was developed to address the complex relationships between humans, their social organizations, and their environments. One of the architects of sociological human ecology was Amos Hawley (b. 1910), a population specialist and professor at the University of North Carolina, Chapel Hill, who argued that human ecology was “the basic social science” (1944, p. 405). Hawley is known for his work on the conceptual and theoretical foundations of sociological human ecology (see Hawley 1986) and the associations among population, the social-political-economic environment, and change in developing nations.
THE ECOLOGY OF HUMAN DEVELOPMENT

Human development is a subfield within the larger field of human ecology. In the 1970s Bronfenbrenner developed the ecological theory of human development, which made use of the general principles of ecology, general systems theory, and human development to explain individual differences in cognitive, biological, and social-emotional development in context. Bronfenbrenner conceived of context as a series of concentric circles, with the individual at the center and each circle representing increasingly complex environments, from proximal to distal, that might affect the development of the individual. Lines of influence are viewed as reciprocal within and between environments. For example, the most proximal environment for a child is the family, represented by parent-child interactions, child-sibling interactions, and marital interactions, all of which may influence some aspect of the child’s development. Just as humans do not live in isolation from nature, a family does not exist in isolation, but operates in a microsystem encompassing those individuals with whom children and parents have regular and ongoing interaction. The third circle represents larger societal institutions, such as schools, businesses, churches, and local government, and the outer circle (the exosystem, or societal institutions that form larger environments of family units) represents larger structural institutions such as state and federal government and international social systems whose policies and laws may affect families and their natural environments. This theoretical framework explicitly recognizes that individuals do not develop in isolation; interactions with families and social groups influence individual development across the lifespan and across generations.

HUMAN ECOLOGY AS A FIELD OF STUDY

As an academic discipline, human ecology has emerged around the world as a field that brings together various aspects of sociology, economics, home economics, anthropology, gender studies, community development, agronomy, and regional planning. The concepts of human ecology fit into the scientific framework of multiple disciplines, all of which examine some aspect of the interactions between humans and their multiple environments. In a 1994 article William Catton suggests that sociologists “must learn to see human social life ineluctably intertwined with other components of ecosystems” if human ecology is to understand and address the problems of human societies (p. 86). Although different, not always overlapping strains of human ecology have evolved in multiple disciplines, the central concepts are strikingly similar, whether pertaining to issues of urban and regional planning, the use of natural resources and sustainable development, or the study of individuals and families. Humans and their social systems, from small to large, must be viewed within their larger environments, including the natural environment, to trace the “chain of effects through ecosystems and human society, and by understanding more generally how people interact with ecosystems” (Marten 2001, p. xv).

Researchers and writers across multiple disciplines agree that human ecology is a valuable framework for studying and understanding the interrelationships between the social systems of humans and the systems of nature. The health of humans, their social systems, and their natural environments may depend on an understanding of this interdependency.

**HUMAN RIGHTS**

The core conception underlying human rights rests on the following premises: (1) all humans have equal rights that derive from the dignity and inherent worth of every person; (2) all humans have rights to freedom and development; (3) the advance of human rights is inherent in the pursuit of world peace, social justice, democracy, and the rule of law; (4) vulnerable groups need special protections; (5) cultural diversity and pluralism affirm persons’ identities; and (6) human rights must be linked with the promotion of sustainable communities and environments. This conception has formally evolved within the international framework of the United Nations, as well as the United Nations’ specialized agencies—the International Labour Organization (ILO) and the United Nations Educational, Scientific, and Cultural Organization (UNESCO). Still, the roots of this conception are everywhere evident, in communities, in peoples’ movements, and increasingly in state constitutions (for summaries see Howard 1995; An-Na’im 2002; Orend 2002; Felice 2003).

**THE ORIGINS OF HUMAN RIGHTS**

The international response to the Holocaust at the end of World War II (1939–1945) was swift and decisive, specifically, the founding of the United Nations in 1945, which in turn paved the way for the formal elaboration of human rights in terms of two distinct but related frameworks (Moore and Pubantz 2006). One framework deals with the most egregious violations, namely, humanitarian law, embodied in the 1949 Geneva Convention on the Prevention and Punishment of the Crime of Genocide, and subsequently in various treaties and statutes, including the 1998 statute that established the International Criminal Court (ICC), which tries individuals who commit crimes against humanity (Robertson 1999).

The second framework deals with fundamental human rights, initially enshrined in the 1948 Universal Declaration of Human Rights (UDHR). This document is extraordinary for many reasons, not the least of which is that it has been affirmed by all of the nearly two hundred member states of the United Nations. (The UDHR does not have treaty status, and therefore is not enforceable.) The philosophical premise, as stated in Article 1, is that “all human beings are born free and equal in dignity and rights. They are endowed with reason and conscience and should act towards one another in a spirit of brotherhood.” The UDHR encompasses three main sorts of rights: (1) political and civil rights that historically evolved in Great Britain, Europe, and the United States; (2) socioeconomic rights and security rights, specifically those rights people have by virtue of being human, such as the right to a job, community and family, food, security, housing, and education; and (3) the rights of vulnerable persons and minority populations.

Subsequently, international treaties have been enacted that are designed to assist nation-states in advancing human rights. These treaties are:

- International Covenant on Civil and Political Rights
- International Covenant on Economic, Social, and Cultural Rights
- Convention on the Elimination of All Forms of Discrimination Against Women
- International Convention on the Elimination of All Forms of Racial Discrimination
- International Convention on the Protection of the Rights of All Migrant Workers and Members of Their Families
- Convention on the Rights of the Child
- Convention Against Torture and Other Cruel, Inhuman, or Degrading Treatment or Punishment

Additionally, the United Nations has promulgated other declarations and charters (without treaty status) dealing with human rights, some of which concern specific groups, such as indigenous peoples, the mentally disabled, and many others. The ILO and UNESCO also have standards for human rights in areas in which they have expertise and authority.

**GLOBAL INTERDEPENDENCE AND HUMAN RIGHTS**

Human rights take on new significance in an increasingly interconnected world in which the gaps in human welfare are widening and all humans are at increased risk owing to the proliferation of weapons, terrorism, and the deterioration of natural habitats (Singer 2004). Just as multinationals acquired the capacities in the 1980s to move their operations everywhere around the globe to find the cheapest labor (Amin 1997), the policies of the World Bank and
the International Monetary Fund put the populations of many poor countries at risk (UNDP 2004). Aggravating these material inequalities, the world’s “haves” are largely white, whereas the world’s “have-nots” are largely non-white.

Another aspect of global interconnectedness is that declines in some national economies have spurred high rates of migration, while affluent countries have increasingly barred migrants’ entry. Furthermore, the rate of decline of the planet’s environment, climate, and biodiversity has accelerated. A sustainable habitat is also a basic human right, but environmental degradation, climate change, hazardous wastes, pesticides, and toxic products all threaten sustainability. On the positive side, the advance of communications has expanded peoples’ own connectedness, which has fostered remarkable cooperation around shared objectives, such as poverty reduction.

HUMAN RIGHTS AS CONSCIENCE AND SOCIAL VALUES
As already implied, human rights are more than formal agreements. They rest on a set of ideals and values. All religious traditions, from the ancient Hindu Upanishads to contemporary religions, have emphasized the importance of duties and obligations, and continue to play an ongoing role in human rights, as do currents in philosophy and ethics (Lauren 2003). The U.S. civil rights movement and other social movements, such as those for gender equality, have played key roles in shaping peoples’ conscience about equality of rights. Liberation struggles against colonial oppressors have also reshaped conscience. The Martinican-born political theorist Frantz Fanon (1925–1961) powerfully captures this in The Wretched of the Earth: “Independence is … an indispensable condition for the existence of men and women who are truly liberated, in other words who are truly masters of all the material means which make possible the radical transformation of society” (1963, p. 310).

CURRENT FRONTS FOR THE ADVANCE OF HUMAN RIGHTS
The advance of human rights is a vision that is increasingly shared by advocates for justice as well as by development specialists, and this is possible because people at the grassroots, community level have been increasingly successful in generating the infrastructures for local nongovernmental organizations (NGOs) that, in turn, form coalitions with international NGOs. In important ways, these relationships have fundamentally transformed development projects, from a top-down approach to complex, collaborative approaches. These coalitions are able to leverage governmental reforms, and sometimes can gain major concessions from local private-sector firms. For example, the French NGO, Dignity International, collaborates with the Nairobi Hakijamii Centre for Economic and Social Rights to reduce poverty in Kenya, and this partnership also has developed models for development that it uses in international education.

Many NGOs already have consultative status with the United Nations, and such relationships are growing and intensifying as the United Nations has embarked on a new and expansive agenda to partner with these organizations, as well as local and state governments and private-sector organizations. The objective is to create layers of engagement, including grassroots engagement, to promote development, human rights, and peace and to stem the causes of human and environmental degradation (Annan 2005). A few examples of NGOs are: Global Rights; the Center for Economic and Social Rights (CESR); Choike-Latin America; Third World Network; and Amnesty International. Very often these NGOs function more as the conduits of expansive networks rather than as single-site organizations. The NGOs that work with the United Nations are also involved in the global World Social Forum, which is an amalgam of a peoples’ social movement, an NGO, and a network of NGOs.

Recent interest centers on the importance of direct, participatory democracy as both a vehicle for governance and an expression of human rights (Beetham 1999; Green 1999). New electronic technologies make it possible for members of a community to participate in democratic self-governance, and the initial pilot projects have been remarkably successful (MacLean 2004). Another approach is based on the idea that credit is a human right. Bangladeshi economist Muhammad Yunus established the nonprofit Grameen Bank in 1976 to give microloans to the very poor in third world countries (Chowdhury 2001). By 2005 Grameen Bank had given out $4,896 million in loans, primarily to women, to start their own businesses. The repayment rate was a remarkable 98 percent. Microloans are not structural solutions for solving poverty, but nevertheless they help to transform the lives of poor women and indirectly benefit their communities.

THE UNITED STATES AND HUMAN RIGHTS
In spite of the great progress that has been made since the initial formalization of the principles of human rights in 1948, there are serious obstacles. A major one has to do with worldwide inequalities of resources, which can be traced to the long-term effects of colonialism, ongoing exploitation by multinationals, and authoritarian governments. Some states are too poor to implement human rights programs, and, besides, many poor states have not yet attained the kind of stable government structures that give people a voice to make
demands for their rights. Yet, paradoxically, the world's most powerful and richest nation, the United States, has been one of the world's worst partners in the international human rights community.

The United States has remained on the margins of the world's human rights community. For example, it rejects the idea that socioeconomic security and cultural identity are human rights. In part, this grows out of ideological conflicts during the cold war; but it is also pragmatic, consistent with U.S. geopolitical ambitions (Tabb 2002). Another explanation is that human rights are not in sync with American values that stress competitive individualism (Blau and Moncada 2005). Indeed, the U.S. Constitution is one of the few in the world today that does not include provisions for socioeconomic rights (Blau and Moncada 2006). In addition, the world's richest nation does not support various treaties to slow the rate of environmental degradation and climate change (Low 1999; Kaul et al. 2003). The United States is one of only a few countries not party to the ICC and during the Iraq War violated the terms of the Geneva Convention, which it has ratified (Hooks and Mosher 2005).

Still, worldwide, the momentum of the human rights revolution has accelerated, possibly because of developments in communications and because of the increasingly grave conditions threatening humans and their habitats. The goal, as often stressed by UNESCO, is “to build peace in the minds of people,” which resonates with the motto of the World Social Forum: “A Better World Is Possible.”

Leading international human rights organizations, such as Amnesty International and Human Rights Watch, have been on the front lines defending peoples’ rights against brutal oppressors and inhuman acts of violence. The very complex and challenging tasks involving securing positive rights, such as the right to a decent job, housing, food, health care, and the right to a culture and to identity require social movements, the engagement of activists, and immense efforts by people in their workplaces and communities. People of color in the United States and elsewhere have played leading roles in such challenging tasks, including roles in the Civil Rights Movement, South Africa's anti-Apartheid struggle, the Zapatista Movement, the Brazilian Landless Movement, and the Malawian shaming campaign against neoliberal policies and foreign investors. In the United States it is significant that an African American, Gay McDougall, executive director of a leading human rights organization, Global Rights, was appointed to serve as UN independent expert on minority issues.

HUMAN SACRIFICE

The practice of human sacrifice has been associated with religious beliefs, famine, and national pride. The term is generally approached with reference to the Aztecs and other Meso-American cultures. Yet human sacrifice has been in practice since the Stone Age and refers to ceremonial slaughter that is performed to achieve a benefit for society, albeit through grisly means.

Evidence of human sacrifice has been found in Denmark, Holland, and Germany. During the Iron Age in these areas, people would be ritually killed by hanging, bludgeoning, strangling, or by having their throats slit. The bodies would then be submerged in a peat bog, where their remains were preserved for centuries. Examples have been found that date back to 3500 BCE. “Bog bodies” have also been found in England. Anthropologists have noted that an overwhelming characteristic of the bodies found was physical deformity, such as extra or missing digits and shortened legs, and it has been postulated that these individuals were thought to have been “touched by the gods,” making them fitting sacrifices.

Between 3100 BCE and 2890 BCE, there was mass human sacrifice in Egypt, for the pharaohs required servants to follow them to the grave. This was also prevalent in Mesopotamia, where servants, guards, and even musicians and grooms consumed poison to follow their kings into death. In the kingdom of Kerma, in Africa, huge pits have been discovered in which some 500 or more people were buried just outside their ruler’s mausoleum. The same rituals occurred in China around the first to second centuries BCE.

Human sacrifice was also practiced in Ancient Greece. Archaeological evidence leading to this assumption has been found on the Isle of Crete. Skeletal remains of several individuals found near Knossos appear to have been put to death in ceremonial ways. One male approximately eighteen years old at the time of death, was trussed tightly, and a decorated dagger was found among his bones. He lay near a trough, which is thought to have been used to collect sacrificial blood, and the body of a woman lay spread-eagled in the southwest corner of the room. Further, what appears to be an altar was festooned with crop-filled vases, alluding to religious ritual.

The Celts also practiced human sacrifice for religious reasons, and their rites were documented in the work of Julius Caesar. According to Caesar, though this point might be contested, the Druids sacrificed murderers, as they believed that only a life offered in atonement for a life taken could appease the gods. Murderers were sometimes sentenced to enclosure in an immense human effigy, which was burned with the criminals inside. Thieves were also sentenced to this fiery death, and when not enough criminals were present to fill the container, innocent people were added to its contents. The Celts also allegedly applied decapitation, throttling, clubbing, or throat slitting, also accompanied by burial in a peat bog. They also killed men by striking them in the back with a sword, and they divined meaning from the ensuing death struggle. In her war against Roman occupation, the warrior queen Boudica impaled vanquished Roman soldiers to honor the gods.

Though the Romans thought these Celtic practices were barbaric, they had in fact carried out their own versions of human sacrifice, though they had ended the practice a century sooner. Yet they still practiced mass execution in the Coliseum during the gladiatorial games, and at a later time Christians would be fed to the lions. Vikings were sometimes buried with slave girls, who were thought to become their wives in Valhalla. Some scholars believe that the women were willing participants who asked for the honor of being ritually stabbed and then burned in the ship with their masters.

The practice of human sacrifice in Meso-America did not begin with the Aztec culture. In fact, evidence has been found that human sacrifice was part of religion as far
back as the first known Meso-American civilization, the Olmecs. The Aztecs are certainly the most well known for their propensity for ritual killings, however. Many of their gods would only be appeased by the flow of human blood. Their most important god was Huitzilopochtli, the Sun God. Aztecs believed that if they did not ritually sacrifice to him regularly, the sun would not rise. In his honor, the high priest would lay a man over the sacrificial stone and cut the beating heart out of his chest, which would then be held up before the attending crowd.

Though this was the most prevalent type of sacrifice, the Aztecs had many gods to satisfy, and they each had prescribed rites. For Xipe Totec, or “Our Lord the Flayed One,” victims were first tied to a tree, then shot with arrows. The ritual required that the victim be flayed so that the skin remained intact. The high priest would then don the skin to symbolize the “new skin” of springtime. For Tezcatlipoca, a young man would be selected and treated royally for one year. At the end of that time, he would be sacrificed. Though these practices seem horrific in modern times, Aztec sacrificial victims were honored to be chosen.

This was also true among the Mayas, who might sacrifice entire losing teams in a ritual ballgame. Criminals were weakened by hunger and then forced to play the game with healthy athletes. The criminal team was soundly routed, with decapitation as the end result. Mayans also sacrificed people to the water god, Chaak, over limestone sinkholes, which were believed to be doors to the underworld.

The Incas also practiced human sacrifice. Yet, unlike early European incidents, Incan sacrifices had to be pure and free of blemishes. Often, a child of the king’s would be sacrificed to strengthen the bond between king and deity. Earthquakes, droughts, epidemics, or the death of kings were reasons for performing the sacrificial ritual, which entailed taking the child to the top of a mountain, where a stone mausoleum would be built. The boy or girl was given a drug to ease the pain, wrapped tightly in ceremonial garments, and buried with many honorific items surrounding the body. Evidence now points to the children receiving a blow to the head, but it is not certain whether it was simply to knock them unconscious or to kill them because the skull fractures found in all the Incan “mummies” are mild.

Though all of these civilizations found reason in what modern man would find a barbaric practice, each civilization had rules for which human sacrifice was required, as well as rules about who the victims would be. This relates to the work of the Italian philosopher Giorgio Agamben, who defines the role of homo sacer or “the citizen,” which is an individual who exists in law as an exile without legal rights or identity. Though such persons can be killed, they may not be ritually sacrificed. Only “bare life,” or individuals without inalienable rights (which relates to political prisoners stripped of citizenship), could be sacrificed by Roman Law. This was not always true in Meso-American civilization. In most cases, it was an honor to be chosen.

Some modern films, such as Mel Gibson’s Apocalypto (2006), which is based on the Mayan civilization, can bring the horror and reality of human sacrifice to life. Though the process of the sacrifice is portrayed accurately in Gibson’s film, other aspects of the practice are not. As stated above, most sacrificial victims went to their doom willingly, in repayment to their gods for life and abundance. To turn down such an offer, or to escape (as Gibson’s character Jaguar Paw does in the film), would have been considered an effrontery to the gods and evoked their wrath upon their entire civilization.

Though the practice of human sacrifice died out after the Conquistadors conquered the New World, it continues in Asia in modern times. In India, a small percentage of followers of the religion Tantrism practice human sacrifice, though this is thoroughly illegal. In one tantric rite, a woman hacked a three-year-old to death to achieve the promise of limitless wealth. In another, a couple who could not have children were directed to murder a child and wash in its blood to assure conception. Though the police have apprehended some of those involved in such cases, it is uncertain whether the practice of human sacrifice will ever end.

HUMANISM

In the widest sense, humanism is conceived as referring to an approach to understanding the world and of living in that world focused first and foremost on humans rather than on God or on nature. Although individualistic, never organized in the form of a movement, and highly variegated and including religious and nonreligious forms, humanisms have exhibited various combinations of freedom and responsibility, learning and observation, reason and values. The term itself only dates from the mid-nineteenth century. The descriptive term, humanist, however, gained wide currency from the late 1400s, and the advent of humanism in the West is usually associated with the classical revival of what has come to be known since the nineteenth century, now often contentiously, as the Italian Renaissance.

Humanists were particularly scholars of the Greek and Latin *litterae humaniores* and engaged in teaching what Cicero (106–43 BCE) had termed *studia humanitatis* based on a liberal education, especially grammar, rhetoric, history, poetry, and philosophy. From early in the fourteenth century, they began to develop a periodization of history that, unlike the continuity experienced in the Middle Ages, was marked by a break with the civilizations of Greece and Rome. Thus in antiquity could be found alternative models for thought and life. Humanist scholars then, with Francesco Petrarca ( Petrarch, 1304–1374) and his friend Giovanni Boccaccio (1313–1375) in the lead and establishing a model widely emulated, were engaged in the recovery of classical texts. Using a philological method, humanists further sought to establish the integrity and the original meaning of the classics in the context in which they were written.

Their passion for antiquity and the proclaimed break with the medieval world presented Renaissance humanists with the problem of reconciling Christian and pagan values in a new historical and intellectual climate. Humanists had attacked scholasticism and, instead of in Aristotle (384–322 BCE), eventually found more congenial philosophical bases in Plato (427–347 BCE). An associated question was that of an active versus contemplative life and the role of the scholar in public affairs. Lino Coluccio di Piero Salutati (1331–1406, chancellor of the Florentine Republic 1375–1406) and the generation of the first half of the fifteenth century tipped the balance toward civic virtue, *civic humanism*, and made Florence the center of humanist studies. The life and work of Leon Battista Alberti (1404–1472) epitomized humanism in the arts. Personifying the Renaissance ideal of the “universal man,” he shared with many humanists a taste for archaeological studies and campaigned for a return to classical models. He advanced realistic representation, systematized perspective, advocated for principles of harmony and the social function of architecture, and put these into practice himself as an architect. The humanists’ interests in perspective, anatomy, and the mathematical bases of proportion and harmony (including that of music) provided material groundwork for the development of the natural sciences as an autonomous domain of knowledge production.

Humanist thought and practice spread widely beyond the original center in Florence to other parts of Italy and, following the invasion of the Italian Peninsula in 1494, extended rapidly to the north as the *new learning*. Education, the key to the discovery of one’s *humanitas*, was a fundamental element in the development of “humanism.” Although the old universities remained in the grip of scholasticism, existing schools were revitalized and new ones established all over Europe to make available a classical education, at least to an elite, and humanist thought prospered in informal groups, correspondence networks, and academies.

While the violence and dislocations of the Wars of Religion of the late 1500s and the attacks on what was considered the heretical idea of personal freedom of thought in the Reformation and Counter-Reformation shook optimism and faith in fundamental human dignity, a renewed sense of confidence and the possibility of progress; a belief in freedom, including freedom of thought and expression, in reason, and in science; and especially an emphasis on a critical outlook marked the eighteenth-century Enlightenment. The corollary to the accent on emancipation and the individual was secularism, indeed an anticlericalism and atheism—different from the accommodation that had satisfied Renaissance humanists. However, the reaction to the French Revolution (1789–1799) offered a sharp rebuff to the way the Enlightenment *philosophes* had envisioned the world. The ineluctable reality of change brought forth contradictory attitudes toward the meaning of “progress” and was translated into the mutually exclusive politics—based on conflicting value sets—of conservatives and radicals. Nonetheless, a belief in the centrality of the human experience and the value of reason and education continued to color nineteenth-century attitudes.

During the late eighteenth century and early nineteenth century, humanism evolved in the Germanies with an emphasis on the individual (even to the detriment of social concerns), the pursuit of classicism in the arts, education reform, and the assertion of classical roots as a fundamental element in the establishment and development of the German state. In England in the early 1880s, the relative merits of the arts (especially schooling in the classics) and the sciences (and the unbiased “truths” they produced) in education were debated by Matthew Arnold (1822–1888), champion of “culture” and a “liberal of the
future,” and T. H. Huxley (1825–1895), Charles Darwin’s (1809–1882) apologist. But their positions were not so far apart; both were needed. Indeed after mid-century, liberal humanism was characterized by a confidence in a future of incremental material and social progress, supported by the emerging social sciences, whose principle actor or “subject,” however, was an autonomous, entrepreneurial, propertied white male. By the end of the century, the new liberalism had co-opted much of both the conservative and radical agendas, and the “common culture” espoused by Arnold was offered as a substitute for equality.

From the late nineteenth century, the European avant-garde contested realist representation (associated with a bourgeois establishment) and the positivist attitude by figuring an internal world, and the twentieth-century wars undermined confidence in an innate human decency and the improvements to be expected from scientific “progress.” Furthermore, over the second half of the twentieth century, the humanist tradition was assailed in a series of developments in the production of knowledge itself. In 1946 Jean-Paul Sartre (1905–1980) extolled existentialism as a humanism, not the liberal/bourgeois humanism with its metaphysical assumptions but a humanism grounded in choice and commitment that linked the individual to the community. In 1947 Martin Heidegger (1889–1976) responded, rejecting humanism and existentialism as metaphysical; instead of the thinking subject, he placed the accent on “being.”

The scope of critiques of the possibility of any universal humanism widened from the 1950s through the mid-1960s. Léopold Sédar Senghor (1906–2001) pronounced négritude, a direct attack on universalizing, Eurocentric culture at the world scale, to be a humanism. Alain Robbe-Grillet, speaking for the nouveau roman and in a debate with Sartre, pointed to the double-edged and paralyzing nature of existentialism that underwrote a hegemony of “man,” a fundamental ideological pillar of modern thought. For Michel Foucault (1926–1984), conceding the influence of Friedrich Nietzsche (1844–1900), not only had humanism as a philosophy reached an end but “man,” a concept of recent invention, would also have to be abandoned (Foucault 1966).

In response to the crisis on the left occasioned by the events of 1956—Hungary, Suez, Nikita Khrushchev’s (1894–1971) secret speech—E. P. Thompson (1924–1993) promoted socialist humanism, which was “humanist because it places once again real men and women at the centre of socialist theory and aspiration … socialist because it re-affirms the revolutionary perspectives of Communism … faith in real men and women” (1957, p. 109). The movement, founded on the early Karl Marx (1818–1883), attracted wide support. In 1964 Louis Althusser (1918–1990) took the couplet to task, associating the terms socialist with science and humanism with ideology by singling out what he called Marx’s break with “every theory that based history or politics on an essence of man” ([1965] 1986, p. 227). Althusser argued that Marx’s “structural” account of social relations gave rise to theoretical antihumanism, which, however, did not rule out ethical commitments. Despite the many valid criticisms, Althusser’s work was the primary source for what came to be known as structuralist Marxism and rendered “humanist” agendas on the left suspect.

By far the most far-reaching development was that of structuralism. Based on the work in linguistics of Ferdinand de Saussure (1857–1913), the structuralisms offered the promise of a new rigor and scientific status, nonreductionist and nonpositivist, for the human sciences. But the emphasis on “constructedness” spelled the end for any humanism founded in essentialist categories, whether human or material. Saussure insisted that languages, systems of signs that express meaning, should be studied not just in terms of their individual parts, diachronically as philologists had, but also in terms of the relationship between those parts, synchronically. The model rehabilitated a version of relational thinking and was appropriated by the social sciences and applied to nonlinguistic phenomena.

The term secular humanism is generally applied to those who embrace humanist principles and contend that these lead to secularism and who reject the supernatural, especially religious faith, while maintaining a belief in the inherent dignity of humankind. It has at times acquired a pejorative tonality, especially when used by religious conservatives to describe nonreligious opponents such as some scientists and intellectuals.

Edward Said (1935–2003) reclaimed the term humanism in a positive sense to describe a practice for what is in the end a defense against inhumanity: historical, rational, and critical thinking (which includes the philological method) informing responsible, activist social agency.

Hume, David

1711–1776

David Hume’s work was crucial in the development of many important social scientific concepts like “the fact/value distinction,” “ideology,” and “economic equilibrium.” Moreover, in a period when the “social sciences” did not yet exist, he envisioned the transformation of the ancient discipline of “moral philosophy” into a “science of man” through the “application of an experimental philosophy to moral subjects” (Hume 1739–1740, p. 4). Such a methodological transformation was essential for the creation of the social sciences.

Hume was born in Edinburgh on April 26, 1711, and he grew up at his family home in the Scottish Borderlands. He studied at the University of Edinburgh, and after rejecting a career as a merchant or a lawyer, he made his way in life as an intellectual and author. He joined a circle of Scottish Enlightenment thinkers, including Adam Smith and Lords Kames and Monboddo, who made Edinburgh the center of their social life. They kept a careful distance both from the Scottish Highlanders to the North—who were prone to violent rebellion against the “powers that be” in London—and the English establishment figures to the South—who were often hostile to ambitious Scots like themselves. Although his philosophical works did not win him fame and fortune, his multi-volume History of England (published between 1754 and 1762) did. During his later years, between 1765 and 1768, he broke through the governmental “glass ceiling” for Scots and was appointed to a number of important diplomatic posts, including charge d’affaires in the British Embassy in Paris and under-secretary of state for the Northern Department (which included Scotland). He died in Edinburgh on August 25, 1776.

Hume’s writings spanned the genres from intricate philosophical studies to belletristic essays and historical narratives. In these texts, Hume created concepts and attitudes that pointed social investigations away from the formal, contractualist framework that dominated Enlightenment social thought and toward a dynamic, empirical approach to human nature.

Hume acerbically made a sharp distinction in the discourse concerning human affairs between “the usual copulations of propositions, is, and is not” and the propositions connecting subject and predicate with “ought” and “ought not.” He insisted that one could not validly deduce “ought” propositions from those stating facts about human behavior alone, and that once “small attention” was paid to this fallacious reasoning, “all the vulgar systems of morality” would be “subverted” (Hume 1739–1740, p. 302). Indeed, the “is/ought” distinction became a starting point for the social sciences in the next century.

Along with this categorical revision of the social world, Hume cultivated in his readers a healthy skepticism for the application of crude causal categories in “the science of man.” Just as Newton rejected the primacy of contact (push-pull) forces in natural philosophy and introduced relational forces—such as gravitational attraction, which operates instantaneously across huge distances—he also debunked the primacy of mechanical causation in the social realm and called for a deeper appreciation of tendential, correlational forces expressed in sympathy, convention, and habit.

Hume also rejected an atomistic conception of the self. He argued that the notion of a simple unified self is a fictional product of an ingrained “propensity to confound identity with relation.” Hume’s “science of man” guards against this propensity and seeks to uncover the complex relations and forces at play in the formation of a self, thus proposing one of the key research themes of the future social sciences. A century later, his recognition of the importance of fictions in social life was to be developed further with the notion of “ideology.”

Hume also emphasized the importance of the precontractual basis of contractual societies by refusing to take the rational, contracting individual as the starting point of social thought. He noted that “two men, who pull the oars of a boat, do it by an agreement or convention, tho’ they have never given promises to each other” (Hume 1739–1740, p. 315), and his new science gave primacy to this level of social cooperation and convention that makes promises and contracts possible.
Although Hume’s work affected the methodology of the social sciences in general, his discourses on commerce, money, and the balance of trade had a major impact on economic thought, both directly and through his influence on Adam Smith.

Hume also recognized that the rules of property ownership and the use of money are “artificial,” that they must be constructed both in an individual’s life and humanity’s history. Consequently, economic “laws,” such as the quantity theory of money, do not automatically apply, but instead require the development of a state where money has “a universal diffusion and circulation” (Hume 1742–1752, p. 294). Moreover, in a fully monetarized society, Hume, like Isaac Newton, differentiated between steady states and accelerating changes of a system’s basic quantities. Thus, he argued that though, in the long run, the price of commodities will be proportional to the quantity of money, “alterations in the quantity of money … are not immediately attended with proportionable alternations in the prices of commodities” (Hume 1742–1752, p. 288). For example, influxes of money, in some circumstances, can stimulate economic activity.

Hume observed that, in a commercial world, money moves across borders in an autonomous manner that makes mercantilist efforts to prevent a country’s loss of specie (e.g., by prohibiting the export of bullion) nugatory and even counterproductive. As long as a nation “preserves its people and industry,” its money supply will tend almost naturally toward an appropriate equilibrium level, just as “all water, wherever it communicates, remains always at a level” (Hume 1742–1752, p. 312).

Finally, although Hume was one of the first major European philosophers to oppose slavery, he was also one of the first to develop the rudiments of a modern race theory claiming to be based on science. His observations of plantation life in the British West Indies convinced him that wage labor was much more productive than slave labor, and that the threat of unemployment had much more disciplinary power for the free workers than the threat of the whip had for slaves (Hume 1742–1752, p. 390). However, since he also claimed to know of “no ingenious manufactures amongst [Africans], no arts, no sciences,” either in Africa or among the freed African slaves in Europe, he was “apt to suspect the negroes to be naturally inferior to the whites” (Hume 1742–1752, p. 208). Thus, he was an influential founder of a biopolitical racism compatible with a regime of waged labor.

In many ways then, Hume is the most “postmodern” of Enlightenment thinkers. An appreciation for his subversive, paradoxical, and militantly secular attitudes and concepts has therefore grown among historians in search of alternative genealogies for the social sciences.

HUME PROCESS

The Scottish philosopher David Hume (1711–1776) made famous the argument that the balance of trade was not worth worrying about because any imbalance would be self-regulating. A trade surplus would lead to higher prices, then to an outflow of gold and silver—and vice versa for a trade deficit. This has come to be known as the Hume process. It is described in the following passage from Hume’s “Of the Balance of Trade” (1748), which is one of the most frequently quoted and among the most influential essays in the history of economics:

Suppose, that all the money of Great Britain were multiplied fivefold in a night, must not the contrary effect follow? Must not all labor and commodities rise to such an exorbitant height, that no neighboring nations could afford to buy from us; while their commodities, on the other hand, became comparatively so cheap, that, in spite of all the laws which could be formed, they would be run in upon us, and our money flow out; till we fall to a level with foreigners, and lose that great superiority of riches, which had laid us under such disadvantages? (Hume [1748] 1985, p. 311)

The popularity of the Hume process arose largely because it was seen as a death blow to the mercantilist fetish for accumulating bullion. Two points about the Hume process struck serious contemporaries. First, Hume

assumes a sudden, large inflow of money to make his point. This is a very different thing from the small (relative to the money stock) and steady inflow advocated by the so-called mercantilists. Secondly, Hume assumes that this sudden inflow is met by an instantaneous adjustment in prices. Otherwise, if the change in, say, wages attracts more labor, there is no reason why the increased money supply could not lead to a greater output and thus avoid inflation. Hume’s “new” result was obtained by (1) altering the substantive position in question from the effects of a steady inflow of gold to that of a sudden inflow, and (2) denying the standard mercantilist assumption of international labor mobility for skilled workers. Hume and the mercantilists differed in that they asked different questions and answered them under different assumptions. Indeed, two of Hume’s correspondents, James Oswald (1715–1769) and the Reverend Josiah Tucker (1712–1799), each provided penetrating critiques and forced Hume to admit, in a later paper, that slow inflation may well help growth.

Hume’s argument is simple and powerful; unfortunately, its implicit assumptions are not obvious. Three such assumptions may be noted. First, the use of the simple quantity theory by Hume, with metal as the sole medium counting as money, was a step backward since the Irish philosopher George Berkeley (1685–1753) had already emphasized the paramount importance of credit a decade earlier. Secondly, Hume assumed that individuals care only about real values, or what is called the homogeneity of degree zero in money and prices. Frank Hahn (1980) clearly points out that even if one grants this assumption for individuals, it does not follow that the economy as a whole will exhibit such homogeneity, unless general equilibrium is unique. Finally, William Darity (1987) showed how the endogeneity of money, which all Hume’s contemporaries were aware of, could make the process neutral or even unstable and hence permit a continual adverse balance of trade. If the gold or silver mines provided metal with increasing returns, then the more prices rose in Spain, the more cheaply they could obtain more precious metal, so that it was actually “economical” for Spain to continue an unfavorable balance of trade. While the popular acclaim for Hume’s argument is not doubted, it largely reflects the difference between an argument that is readily understood by the educated public and one acceptable to those who devote care to such issues.

HUMILIATION
The field of humiliation studies emerged in the early twenty-first century. In 2001 the Human Dignity and Humiliation Studies (HumanDHS) network (http://www.humiliationstudies.org) was founded as a global consortium of distinguished academics and practitioners with the aim to create a new multidisciplinary field that bridges academia with practice and incorporates scholarship from anthropology, history, philosophy, political science, social psychology, and sociology.

The phenomenon of humiliation is rapidly gaining visibility and significance. Expectations of equal dignity and opportunity rise as people come closer together, both physically and digitally, in a globalizing world. Coupled with the spread of the human rights message, any attempt to lower the expectations of any one group becomes a humiliating offense against all groups and humanity in general. The first sentence in Article 1 of the Universal Declaration of Human Rights reads, “All human beings are born free and equal in dignity and rights.”

Few researchers have studied humiliation explicitly. In many cases the term humiliation has not been differentiated from other concepts. In the work of HumanDHS, in contrast, humiliation is addressed on its own and is differentiated from other concepts: humiliation is, for example, not regarded simply as a variant of shame. Shame is often accepted as prosocial humbling—human rights

advocates, for instance, frequently use shaming techniques to make people abide by human rights—while humiliation describes a hurtful experience that typically is rejected as an illegitimate violation by the victim. (However, a special type of shame—unacknowledged and bypassed shame—as been described to be emotionally destructive.)

In today’s mainstream language, the word humiliation is used threefold. First, the word humiliation signifies an act; second, a feeling; and third, a process: “I humiliate you, you feel humiliated, and the entire process is one of humiliation.” This triple meaning of the word humiliation complicates its use; sometimes humiliation indicates the feeling of a victim, sometimes the act of a perpetrator, sometimes the entire process from act to feeling.

The core meaning of humiliation entails a downward push, down to the ground, to earth, as derived from the Latin word humus. This push can be perceived as a hurtful violation, or not, depending on the overall societal, cultural, and psychological framework. In human rights–based contexts being pushed down and held down is perceived as a violation that will lead to suffering and rage that may be turned inward or outward. Rage and fury turned inwards render feelings of depression, abandonment, anomie, and alienation. Rage and fury turned outward feed violence, including mass violence.

Yet, prior to the human rights movement, being put down was often embedded into a culture of ranking in which higher beings were expected to show lower beings their due lowly place. In that case being put down is not perceived as a violation and therefore does not elicit the same consequences as previously described. Human rights delegitimize such practices and empower the downtrodden to invoke humiliation.

In other words, the differentiations one uses today are historically recent. According to the Oxford English Dictionary, the earliest recorded use of to humiliate, meaning to mortify or to lower or to depress the dignity or self-respect of someone, did not occur until 1757. Up to 1757, the words to humble and to humble were used rather interchangeably. It is in fact with the emergence of human rights ideals of equal dignity for all that these two words move into diametrically opposed directions.

Humiliation is a complicated concept. Not always does a person witness a humiliator and a humiliatee. For example, help may humiliate. In that case there is a benevolent helper on one side and no ill-intentioned perpetrator at all. Or, neither actor nor victim may define a situation as humiliating, only a third party. The social worker wants to rescue the battered wife, but she claims that the beatings are her husband’s way of loving her. Then, one may expect that humiliation is always avoided, however, some people seek it, for example in sadomasochism or religious rites. Thus, humiliation is an act, an emotional state, and a social mechanism, with a broad relevance, from anthropology, sociology, philosophy, social and clinical psychology to political science.

Phenomena such as global terror may be explained as an outfall of global clashes due to humiliation rather than of clashes of civilizations. Global and local terror and violence may be linked to humiliation rather than to “unexplainable evil.” Conflicts of interest over scarce resources, often identified as a source of violent conflict, may very well lead to cooperation. It may be precisely humiliation that hampers cooperation. Many people profess their love for peace, while being unaware that their fear of humiliation and their wish to resist humiliation may foreclose peace. A Somali proverb makes this point very clear, “A man deserves to be killed and not to be humiliated.”

Adolf Hitler imagined future world domination and humiliation from the World Jewry (Weltjudentum), and the Holocaust was his atrocious attempt to “prevent” future humiliation. Also in Rwanda, it was imagined humiliation in the future that was “prevented” by genocide. Nelson Mandela, in contrast, made constructive use of the energy contained in the experience of humiliation brought about by apartheid. After twenty-seven years of humiliation in prison, he could have unleashed genocide on the white South African elite. However, he did not. He refrained from instigating cycles of humiliation and instead promoted constructive social change that included the perpetrators.

The solution is egalization, brought about in a Mandela-like fashion. Egalization, a word coined by Evelin Lindner in the context of HumanDHS, has been designed to match the word globalization and at the same time differentiate it from words such as equality, equity, or egalitarianism. The main point of egalization is the true implementation, beyond mere rhetoric, of equal dignity for everybody as stipulated in the Human Rights Convention. Only a world that combines globalization with egalization, and thus prevents and heals the violent outfalls from dynamics of humiliation, can be expected to be sustainable and decent.

HUNGARIAN REVOLUTION

The events in Hungary in October to November 1956 have been characterized both as an uprising and a revolution. The revolt was spontaneous, and its adherents came from diverse political and social backgrounds with disparate motivations. However, the speed with which the unrest spread across the country evidenced a commonly held and deep-seated bitterness over the nation’s political and economic plight. Moreover, most of those involved blamed the crisis squarely on the Soviet-dominated regime that had been in place since 1949, and demanded the removal of Soviet forces from Hungary as well as the reintroduction of a multiparty political structure. The magnitude of popular opposition and the general objective of abolishing the existing system merit classifying the events of 1956 as a revolution.

Despite its failure, the revolution had significant effects. In the short term, it did result in greater consolidation of Soviet control over both Hungary and the region. With Moscow’s backing, the newly installed leadership under János Kádár (1912–1989) violently quashed the rebellion, executing hundreds, including the reformist prime minister Imre Nagy (1896–1958), and imprisoning thousands, thus eliminating all overt political dissent. Regionally, the revolution forced Soviet leader Nikita Khrushchev to be more cautious in encouraging East European Communist rulers to pursue reforms. However, the long-term effects of the revolt were more significant. The crisis exposed the ideological bankruptcy of Soviet-led communism and the brutality of Moscow’s methods, and served as a permanent symbol for the causes of self-determination and independence in the region.

Half a century later, scholarly debates persist about many aspects of the revolution, although the opening of archival records in recent years has helped to resolve important issues. In Hungary the scale of the revolt, the manner in which it unfolded, the behavior of various groups in different parts of the country, and the methods employed to fight the Soviets are all well known. Of particular interest among the new findings are records describing the actions of Nagy and his colleagues in the temporary government. Nagy emerges as a figure both complex and courageous, if ultimately inadequate to the task, who was thoroughly underestimated by both Moscow and Washington. The circumstances surrounding his fate are more fully understood as well: Kádár, not the Soviets, pressed for his execution, which finally took place in 1958.

The archives further explain a great deal about decision making in Moscow. Handwritten notes of Soviet Presidium meetings by Vladimir Malin, head of the General Department of the party, record key debates over whether to acquiesce to the changes in Hungary or to suppress the revolt. Khrushchev and his more moderate allies clearly hoped to avoid a major intervention, and the Kremlin appeared to be on the verge of ordering a troop withdrawal from Hungary (a public declaration to that effect appeared on October 30) when he suddenly reversed course a day later.

The U.S. role is also clearer. The revolution caught the White House by surprise, and the Eisenhower administration came under criticism from certain quarters for its passive reaction. Yet suspicions have lingered that the United States quietly undertook certain covert operations such as unleashing trained émigré units and providing weapons to the rebels. Recently declassified internal records from the Central Intelligence Agency make clear, however, that no such activities took place, nor did senior White House officials contemplate them. Furthermore, it is well established that President Eisenhower opposed any actions that might provoke a direct conflict with the Soviet Union.

Yet, a number of questions remain unanswered. Kádár is still a controversial figure in Hungary, and his exact motivations in accepting the role of the Kremlin’s agent of repression are still in dispute. Scholars also continue to discuss the most contentious aspect of U.S. involvement—Radio Free Europe (RFE). RFE tapes from the period confirm that the organization broadcast statements that at the very least encouraged insurgents to take action. Although recent analyses downplay the impact of those broadcasts, there is some disagreement over whether U.S. officials authorized them and to what degree they were responsible for inciting Hungarians to risk their lives in the revolution.

Regarding the Soviet response, although we now know better which issues concerned Khrushchev—the descent into chaos inside Hungary, the Suez crisis, domestic political considerations and possibly China’s views—it remains unclear exactly which of these, or what combination of these, ultimately changed his views. A related difference of opinion exists over whether and how the Suez
crisis affected events in Hungary beyond influencing Khrushchev’s thinking. Underlying these questions is the fascinating debate over whether the crushing of the revolt was inevitable or whether different choices by the rebels, Nagy, members of the Soviet leadership, or even the Americans might have averted the tragedy.

HUNTER, FLOYD

1912–1992

Born into a farm family of meager means, Floyd Hunter came of age during the Great Depression and early on displayed populist tendencies. His experiences as a social worker and administrator heightened his wariness of business. Subsequent to receiving his undergraduate degree (1939) and his master’s degree in social service administration (1941) from the University of Chicago, Hunter began work with the United Service Organizations. He came to Atlanta, Georgia, in 1943 and headed that organization’s southeast office, shifting to work with the Atlanta Community Council from 1946 to 1948. Fired from the latter position as a controversial figure, Hunter had acquired an insider’s understanding of how communities deal with social problems.

He next undertook graduate study in sociology at the University of North Carolina and returned to Atlanta for field research, completing his dissertation and then converting it into a reputation-establishing first book, Community Power Structure: A Study of Decision Makers (1953). A work about Atlanta, it inspired a surge of community leadership studies. Hunter’s later research extended to state and national levels, but subsequent work never matched the pathbreaking impact of Community Power Structure. Within political science a pluralist school of thought attacked Hunter’s approach, blunting its influence within this area of academia.

Some ambiguity is attached to the term power structure. It is often used simply to refer to a group deemed to be top leaders. True to his training in sociology, Hunter, however, coined the phrase to refer to stable relationships through which major policy decisions are made for the community. For Atlanta in the immediate postwar years, Hunter’s central finding was that reality deviated sharply from the ideals of representative government, with policy making centered in arrangements around the city’s top business leaders.

Critics attributed to Hunter the view that Atlanta was run by forty individuals. This, however, is an oversimplification of both his method and findings. Hunter relied on knowledgeable insiders to compile and refine a list of top leaders, ten from each of four sectors of community life. He then used a sociometric technique to identify patterns of interaction. For good measure, he added an examination of particular issues, and he did a separate analysis of leadership within the black subcommunity and how it related to Atlanta’s white leadership. The logic of Hunter’s research was not about determining a specific number of top leaders, but about examining the relations among different sectors and how those interrelations affect policy making for the community.

In contrast with Robert S. Lynd and Helen M. Lynd’s (1929, 1937) earlier works on Middletown, in which business is accorded a pervasive form of influence based on the domination of business values, Hunter’s study of Atlanta was specifically concerned with the ability of business-centered leadership to manage social change through
a structured capacity to set the policy agenda. Atlanta's business leaders led lives quite insulated from the concerns faced by ordinary citizens, especially the poor. Nonetheless, Hunter found that through their control of economic assets, their central role in civic matters, and their ability to use informal channels of interaction among themselves to reach consensus, they formed a relatively closed leadership group.

Later works, including his follow-up study of Atlanta, *Community Power Succession: Atlanta's Policy-Makers Revisited*, were variations on this initial theme. Hunter taught at the University of North Carolina until 1960, then moved to California, mixing social-research consulting with numerous visiting faculty appointments. He died in 1992.

**HUNTINGTON, SAMUEL P. 1928–**

Samuel Phillips Huntington, born April 18, 1928, has contributed controversial insights to contemporary political debates. Huntington graduated from Yale University at the age of eighteen. After serving in the military, he graduated from Harvard University with a doctoral degree at twenty-three years of age. Huntington's most notable contribution to the field of political science is the book *The Clash of Civilizations and the Remaking of World Order*, an instantly controversial success. Originally conceived as an article contribution to *Foreign Affairs* magazine in 1993, the author expanded the piece due to popular demand. In this article, Huntington's primary focus is the decline of nation-centered unity. He argues that instead of focusing on nationalistic principles as had been the precedent before the end of the cold war, states have begun cooperating based on cultural orientation. The author predicts that distinct and violently competitive civilizations will emerge. According to Huntington, the countries of Europe and North America should learn to unite. Their cultural foundation is based on moral principles and a commitment to what he calls "Western" values: peace, freedom, and democracy. Should economic warfare divide European and North American countries, the author believes a shift in the geopolitical balance of power will take place. It is Huntington's belief that insofar as these democracies prevailed in the twentieth century, the "Chinese/Sinic/Confucian" and the militant Islamic world will dominate the twenty-first century. The polemical nature of Huntington's theses has opened his arguments to vituperative criticism. His critics label this "civilizations thesis" as single-minded and parochial.

In Huntington's judgment, the Hispanic community in the United States stands accused of a refusal to assimilate and of a wholesale rejection of America's English language, creeds, and values. In *Who Are We? The Challenges to America's National Identity*, published in 2004, the author asserts that Mexican Americans refuse to adopt American identities. To Huntington, this is of particular concern because of their high reproduction rate, which may result in a population that will divide America when it desperately needs cultural unity in the face of mounting

Clarence N. Stone
international challenges. Huntington’s premise is America’s distinctiveness: the perception that the United States has triumphed in the past as a result of the maintenance of the Protestant work ethic and the religious unity originally instilled by the founders of the nation. An erosion of this commonality, he argues, bodes ill for the future.

Huntington also wrote American Politics: The Promise of Disharmony, published in 1981. In this monograph he argues that a divide exists between the political ideal and the political reality in American politics. Binding Americans together throughout U.S. history has been their love of freedom and their contempt for totalitarian dictatorships. Huntington believes that Americans revolt socially every third generation in protest of the bitter compromise of promoting freedom while supporting hierarchies of power to maintain national security. Asserting that protests will continue to grow in strength, he once again raises his central theme: In order to perpetuate democratic ideals and the spread of freedom, the United States must assert itself forcefully abroad to reassure the public at home of its morality and greatness.

In 2005 a new edition was published of Huntington’s 1957 work, The Soldier and the State: The Theory and Politics of Civil-Military Relations. For Huntington, central to the politics of military affairs is the liberal double standard. Political liberals vociferously announce their intent to diminish violence, genocide, and the expansion of destructive armaments, according to his observations, but they contradict these objectives by seeking to restructure the U.S. military and weaken it from within. They seek to apply a civilian control over military matters, thereby reducing the ability to conduct wars effectively and to diminish threats to America. Huntington suggests that national security can only be ensured when conservative frameworks are applied to military affairs. This entails continuously maintaining a state of preparedness.

Huntington is the Albert J. Weatherhead III University Professor at Harvard University.

HURSTON, ZORA NEALE

1891–1960

Zora Neale Hurston was born almost a decade earlier than she declared in her autobiography, Dust Tracks on a Road (1942); accordingly, to biographer Valerie Boyd, she was a woman “ahead of her time” (Boyd 2003, p. 17). Hurston is noted today for her contributions as a literary author, folklorist, and anthropologist. She stands as a “first” in many arenas, including as the first African American woman to graduate from Barnard College in 1928 at the nontraditional age of 37. As a Barnard student, Hurston was able to take classes at Columbia University, where she flourished. “Under the kind eye of the preeminent Franz Boas, considered the father of American anthropology, Hurston found support for her folklore research,” wrote biographer Irma McClaurin (2000, p. 18). It was Boas who encouraged her to use “the clarifying monocle of anthropology” to salvage and analyze the superstitious stories and “down-home lies” she remembered hearing as a child in Eatonville, Florida, an all-black town founded in 1887 near Orlando (Boyd 2003, p. 115). This thriving community of African Americans who supported and respected each other, according to Boyd, became a vital source of inspiration for Hurston, who lived there from the time she was almost two years old. Her father was elected mayor in 1897 and then again in 1912. Hurston eventually studied the rich folk culture of her hometown, recognizing the priceless contribution it could make to the field of cultural anthropology. Memories of the tales she heard on her neighbor Joe Clark’s storefront porch influ-
enced Hurston’s fiction and are evident in stories like “Sweat” and “Possum or Pig,” both published in 1926. That same year she also published *The Eatonville Anthology,* “an engaging amalgam of folklore, fiction, and Eatonville history” (Boyd 2003, p. 139).

**A NEW DAY: THE HARLEM RENAISSANCE**

There is some debate over when the Harlem Renaissance began. Some list 1919 as the starting date and its demise during the mid-1930s. Also, there is some question as to where it started since Hurston and other Renaissance writers, including Angelina Grimké (1805–1879), Jean Toomer (1894–1967), Sterling Brown (1901–1989), Richard Bruce Nugent (1906–1987), and William Waring Cuney (1906–1976), began meeting in Washington, D.C., in the early 1920s as members of “the Saturday Nighters” at the home of the poet Georgia Douglas Johnson (1886–1966). Into their midst came influential writers and scholars such as W. E. B. Du Bois (1868–1963), Alain Locke (1886–1954), and James Weldon Johnson (1871–1938), all of whom traveled between Washington, D.C., and New York City and had great influence in shaping the Renaissance. As a result of these interactions with “the gifted, the famous, and the wannabe famous,” Hurston, who didn’t arrive in Harlem until 1925, had no problem settling in and finding her place among the artists and writers who dubbed themselves “the Niggerati” (Boyd 2003, p. 116). It was not an easy time for a single black woman to establish herself as a writer; during the 1920s African American women were most often employed as domestic help or store clerks. “And so, in the 1920s,” wrote McClaurin, “we must see Zora as a woman who lived against the grain, … perfect[ing] a hat-wearing, cigarette smoking, gun-toting persona that was tremendously at odds with the ideals and standards of traditional womanhood of the time—for both black and white women” (2003, p. 5).

**RESEARCHING THE AFRICAN DIASPORA**

From the start of her research, Hurston worked to gather perspectives from the African Diaspora—the scattering of African people throughout the Americas—collecting black folklore in the U.S. South, the Bahamas, Haiti, Jamaica, and the Honduras. Hurston believed that, despite slavery and its resulting social inequality, African-descended people retained and continued to create a rich canon of stories, myths, and “lies,” all communicated through evocative language and performance—what she called “the greatest cultural wealth of the continent” (Kaplan 2001, p. xxiii). It was also Hurston who recognized the “logic” of studying the culture of blacks in the South and the Caribbean as part of a continuum. In fact, Hurston had a desire to create a field of study around the American Negro, as she wrote in a letter to the anthropologist Melville Herskovits (1895–1963): “You fully appreciate how much there is to be done when you realize that there is no real curricula for those Anthropologists who wish to study the Am. Negro [sic]. Papa Franz knows the Indian, etc, but there was nothing to help me in my study of the Negro…. Suppose we set out to create the same thing for the Negro at Northwestern as Boas has done for the Indian at Columbia” (Hurston 2002, p. 372). In 1936, Herskovits was not only unsupportive of Hurston’s overtures, but he also tried to steer her away from conducting research in Jamaica and Haiti, where she eventually finished the manuscript for *Their Eyes Were Watching God,* published in 1937.

**HURSTON AS DRAMATIST, ETHNOGRAPHER, AND WRITER**

Funded by a grant from Carter G. Woodson’s Association for the Study of Negro Life and History in 1927, and later a contract with white patron, Charlotte Osgood Mason (1854–1946), between 1927 and 1929 Hurston traveled to Florida, Alabama, Georgia, New Orleans, and the Bahamas in search of “authentic” Negro expressive folk culture (Kaplan 2001, p. xxii). She wrote to the author Langston Hughes (1902–1967) of her desire to write at least seven books based upon these ethnographic journeys, but she published only one, *Mules and Men,* in 1935. She also presented her patron, Mason, with a manuscript entitled “Negro Folk-tales from the Gulf States,” published posthumously in 2001 as *Every Tongue Got to Confess.* Much of Hurston’s folklore material from her 1920s fieldwork seems to have vanished, although some of the rich data surfaced in her collaboration with Hughes on the play *Mule Bone* in 1930.

The 1930s proved a prolific period for Hurston: She published “Hoodoo in America” in the *Journal of American Folklore* in 1931, conducted ethnographic research on West Indian Obeah practices in 1936, published *Tell My Horse,* completed and published in 1938. In 1939 Hurston joined the Federal Writers Project (FWP), where she produced “consummate essays and commentary about Florida and folklore,” demonstrating that she was “a serious anthropologist whose career had just hit its stride” (Bordelon 1999, p. x). During this time, according to
biographer Carla Kaplan, she also staged folklore productions.

**A TRAGIC ENDING**

Numerous tragedies struck Hurston in the 1940s. The WWP project ended, as did her second marriage (1939–1943) to Albert Price III. For a brief time in 1944, Hurston was married to James Howell Pitts, and published “My Most Humiliating Jim Crow Experience.” Always intrigued by the Diaspora, Hurston traveled to the British Honduras in 1947 to study black communities. While there she wrote Seraph on the Suwanee. Published in 1948, the novel contains excerpts taken from Hurston’s “FWP field notes and placed … in the mouths of her novel’s characters” (Bordelon 1999, p. x). In 1948, Hurston was accused of molesting a minor. Although the charges were dismissed a year later, the event took its toll.

Between 1950 and 1959, Hurston worked a series of odd jobs—journalist, librarian, maid, and substitute teacher—and published some memorable essays along the way, including the controversial “What White Publishers Won’t Print” in the *Negro Digest* and her last published story, “The Conscience of the Court,” in the *Saturday Evening Post*, both appearing in 1950. In the early part of 1959, Hurston suffered a stroke. By October she was forced to move into the St. Lucie County Welfare Home.

On January 28, 1960, the once-famous Hurston, noted anthropologist, folklorist, novelist, playwright, and preserver of black folk culture, died penniless. She was buried in an “unmarked grave in the Garden of Heavenly Rest, Fort Pierce” (Gates 1990, p. 311). Interest in Hurston revived in 1975 with the publication of Alice Walker’s *In Search of Zora Neale Hurston* in *Ms.* magazine. In 2005 Hurston’s novel *Their Eyes Were Watching God* became a television movie starring Academy Award–winning actress Halle Berry. Hurston held a consummate passion for and commitment to the preservation of African American folk culture. What she contributed to anthropology was a body of scholarship that sometimes challenged the literary, social science, and social conventions of her time but illuminated the “figurative capacity of black language” in a manner yet to be replicated (Gates 1990b, p. 212). Hurston’s life, her strikes against social conventions, and her love for black language and black folk culture in all its expressive manifestations continue to inspire into the twenty-first century.

Hurwicz, Leonid

1917–

Leonid Hurwicz is among the leading mathematical economists of his generation. He utilized game theory, mathematical programming, dynamical systems, and topology, among many other fields of mathematics, contributing to the development of those fields and to their application to economic theory and policy. Hurwicz was born in Moscow to Polish Jewish parents in the year of the Russian Revolution. His parents therefore moved with him to Warsaw in 1918. Hurwicz shared the educational experience of all Jewish boys in Warsaw, likely attending a gymnasium, or high school, with further education in a yeshiva. He entered the University of Warsaw in 1933, graduating in 1938 with a degree in law, having concentrated in political economy. In 1938 Hurwicz traveled to Britain to study at the London School of Economics and Political Science under neo-Austrian economists Lionel Robbins (1898–1984) and Friedrich Hayek (1899–1992). Importantly for his subsequent career, a recent member of the faculty was Polish socialist refugee Oskar Lange (1904–1965), who had left the University of Krakow in 1935. In 1939 Hurwicz studied at the Postgraduate Institute of International Studies in Geneva, where he attended a seminar conducted by Jewish Austrian economist Ludwig von Mises (1881–1973).

At the suggestion of Lange, Hurwicz migrated to the United States in 1940. He went to Chicago, which had a large Polish immigrant population, and studied for two years at the University of Chicago, where Lange was on the economics faculty. In 1941, while a student at Chicago, Hurwicz also studied at Harvard University under Wassily Leontief (1906–1999), whom he met at the Cowles Commission conference in Colorado Springs in 1940.

In January 1942 Hurwicz was recruited to the staff of the Cowles Commission by research director Theodore O. Yntema (1900–1985). In this position, Hurwicz assisted Lange in statistical testing of business-cycle theories, and worked with Yntema and Joel Dean (1906–1979) as executive director of the project on wartime price controls of the Committee on Price Determination of the Price Conference of the National Bureau of Economic Research (NBER). He would remain on the commission staff until 1961.

In 1941 Hurwicz secured a research and teaching fellowship at the Massachusetts Institute of Technology. The following year, he taught mathematics and statistics to members of the U.S. Army Signal Corps at the Illinois Institute of Technology. Simultaneously, and continuing to 1944, he was hired as a faculty member of the Institute of Meteorology at the University of Chicago and an instructor of statistics in the Economics Department. He was awarded a Guggenheim Fellowship for the 1945–1946 period. From 1946 to 1949 he served as associate professor of economics at Iowa State University in Ames. From 1949 to 1951 Hurwicz served as professor of economics at the University of Illinois. He then became professor of economics and mathematics at the University of Minnesota Graduate School of Business, a position he retained until retiring around 1987.

In the 1940s and early 1950s Hurwicz presented several papers to professional associations in mathematics, statistics, and economics, and he published papers in the journals of these associations and in a book published by the Cowles Commission. Most of these papers were on statistics. His focus shifted to game theory in 1953, then in 1955 he began to focus explicitly on economics, publishing articles on resource allocation, including a review of Leontief’s book on input-output analysis. In 1956 Hurwicz and Kenneth Arrow began a long collaboration that would continue beyond the 1970s. In 1958 Hurwicz and Arrow published an article on the stability of equilibrium in a general equilibrium system. Hurwicz’s first book was published in 1958, when he was forty-one years old. It was a joint effort with Arrow and Hirofumi Uzawa.

In 1955 Hurwicz published a Cowles Commission discussion paper titled “Decentralized Resource Allocation,” in which he initiated his research on economic information theory. In this paper, he was stimulated by Hayek’s polemic with the socialists on the feasibility of calculating equilibrium prices and quantities in the absence of a market, due to the absence at the center of decentralized price information. Hurwicz’s 1955 paper developed from the argument by Hayek and Mises that only a decentralized (i.e., market) system could manage a modern economy. His subsequent writings in this area represent extensions of this argument in different mathematical directions. Arrow and Hurwicz later observed that the Hayek-Mises position implied that information was not a costless resource, but that a perfectly competitive market minimized this cost.

macroeconomic models are specified as linear models. Hurwicz was a leader in research on estimating the parameters of the nonlinear model. The parameters were the prices at which demand equaled supply in each of hundreds of industries. His motivation for this research was not only theoretical, but stemmed from his work in the 1940s at the Cowles Commission, where he directed the program to study empirically, as well as theoretically, the wartime price-controls program, the nearest that the United States has ever come to comprehensive central economic planning.

Given a system of differential equations, several questions may be posed: Does a solution to the system exist? Is any given solution, once found, a stable solution? And what mathematical tools can be used to answer the first two questions? Hurwicz did not contribute to the literature on the existence problem. Between 1958 and 1960, he and Arrow published four articles and one book on the stability issue. In these publications, they attempted to extend the stability conditions for a single market to the general equilibrium case of multiple markets. Arrow and Hurwicz developed an analysis that economist Don Patinkin (1922–1995) called “stability in the large,” defined as “the conditions that make it possible for the Walrasian à la tâtonnement to bring the economy to an equilibrium from any point whatsoever.” They simplified this task by reducing the economy to a two-good economy (Hurwicz and Arrow 1958, p. 522). A recent answer to the third question is phase diagrams, which assist in solving systems of differential equations. Hurwicz did not use this technique in any publications through the 1970s.

Hurwicz’s work in linear and nonlinear programming was done largely in the 1950s with Arrow. Most of this research focused on the development of the gradient method of finding a solution to the programming problem of optimizing a function under constraints. The gradient method was intended to solve concave functions, rather than linear functions. The project found that the gradient method was inferior to the simplex method, an algorithm developed by George Dantzig (1914–2005).

Hurwicz is considered the father of information theory in economics. He showed clearly that information and its distribution within economic institutions was critical to decision making in resource allocation. This work provided additional theoretical underpinnings for transfer pricing in state enterprises and large complex private corporations.

Hussein, King of Jordan

1935–1999

Hussein bin (“son of”) Talal, the longest-ruling king of Jordan, was born in November 1935 in Amman, Transjordan. His grandfather, Abdullah (1882–1951), ruled as emir over a sparsely populated, impoverished principality formally under the British administration in neighboring Palestine. Abdullah came from the Hashemite family of Mecca, which led an Arab national-
ist uprising against Ottoman Turkish rule during World War I (1914–1918). After the defeat of the Ottomans, Britain created Transjordan, installing Abdullah as its proxy ruler in the strategically important area. Abdullah later became king upon the country’s formal independence in 1946. Significantly, Jordan fought against Israel during the first Arab-Israeli War of 1948. Although the war ended as a disastrous defeat for the Arabs generally, and the Palestinians particularly, Abdullah expanded his kingdom when in 1950 he formally annexed the portion of Palestine that came to be known as the West Bank.

Young Hussein bin Talal was close to his grandfather and became heavily imbued with his family’s self-proclaimed legacy as the vanguards of Arab nationalism and protectors of the Palestinians. Educated in Britain, Hussein also adopted Abdullah’s pro-Western orientation. Hussein was by Abdullah’s side when the monarch was assassinated in Jerusalem by a disgruntled Palestinian in 1951. After the brief rule of his father, Talal (1909–1972), the seventeen-year-old Hussein formally became king in 1952, although he was not enthroned until reaching the age of eighteen in 1953.

Until his death in 1999, King Hussein’s long rule was noteworthy both for Jordan’s remarkable socioeconomic development and for the tremendous strategic challenges that buffeted the country. These included the powerful surge of anti-Western Arab nationalism in the 1950s and 1960s that nearly led to a military coup in 1957; the ongoing Arab-Israeli conflict, especially the disastrous Arab defeat in 1967 that saw Israel occupy the West Bank; and the subsequent rise of Palestinian nationalism and demands for an independent Palestinian state, free from both Israeli and Jordanian control. With its large Palestinian population, Jordan was particularly affected by the latter. The demands of Palestinian guerrilla for renewed war with Israel after 1967 and for the overthrow of Hussein led to the gravest crisis the king ever faced—open war in his country between the Jordanian army and Palestinian fighters in September 1970 and again in July 1971 that resulted in the Palestinians’ defeat.

In this and other trials, King Hussein proved a consummate political survivor. Domestically he survived economic downturns and demands for greater democracy. As a monarch who reigned and ruled, Hussein both could clamp down hard on political opposition (as when he banned political parties and declared martial law in 1957) or liberalize the political system (as when he ended martial law and allowed the return of political parties and elections starting in 1989). In terms of foreign policy, he managed to weather threats from powerful neighbors and foes such as Syria, Iraq, the Palestine Liberation Organization (PLO), and Israel by cozying up to one or more of them at the expense of the others. Hussein’s maneuvering led him to a rapprochement with the PLO by the 1980s, a renunciation of claims to the West Bank in 1988, support for Iraq during the 1991 Gulf War, and a peace treaty with Israel in 1994.

King Hussein died of cancer in Amman in February 1999, and was succeeded by his eldest son from his first marriage, Abdullah.

HUSSEIN, SADDAM
1937–2006

Saddam Hussein was born on April 28, 1937, in the northern town of Tikrit, Iraq, to a landless family. His mother was widowed and lost Hussein’s older brother while she was pregnant with Saddam. After his mother remarried, the family moved to the tiny village of Uja, a few miles south of Tikrit, where they led an impoverished life. His mother had three more children with her new husband, and Hussein’s stepfather preferred them over him. Being fatherless, Hussein was exposed to abuse on the part of the village’s children. His parents did not want to send him to school, but when he turned ten he insisted on moving to Tikrit to stay with his maternal uncle, Khayr Allah Tilfah, and attended primary school there. In 1955 he moved with his uncle’s family to Baghdad to attend high school, but before graduating he became involved in political activities, having joined the revolutionary underground Baath Party in 1957. Later, as an exile in Cairo, he completed his secondary education and took some classes in law. As vice president of Iraq, he took private lessons in law, but he never completed his formal education.

On July 14, 1958, General Abdul-Karim Qassem (1914–1963) toppled the monarchy in Baghdad and established a semibenevolent dictatorship. Within weeks
it became clear that Qassem's approach to Arab unity was opposed to that of the Baath Arab Socialist Party, Hussein's chosen venue for political action. With the support of Iraqi communists, Qassem objected to unification with Gamal Abdel Nasser's (1918–1970) Egypt, and he placed a heavy emphasis on Iraqi identity and Iraqi interests, rather than on pan-Arab ideology and practice. In October 1959 Hussein participated in a failed assassination attempt on Qassem's life. Hussein and his collaborators managed to wound the Iraqi dictator, but Hussein himself was wounded in his thigh and one of his team was killed, apparently from bullets shot by their own colleagues. Hussein managed to escape to Syria, an odyssey that became the object of a heroic myth weaved by his media after he became president. In Damascus he met the founder and chief ideologue of the Baath Party, the Syrian Christian intellectual Michel Aflaq (1910–1989). Aflaq was impressed by Hussein's audacity and strength of character, and thereafter Hussein's position in the party was assured. Hussein soon left Damascus for Cairo, where he lived a modest life sponsored by Nasser.

**BAATH PARTY COMES TO POWER**

On February 8, 1963, the Baath Party, in collaboration with a few army officers, staged a coup d'etat and killed Qassem. Hussein immediately left Cairo and arrived in Baghdad, where he became a midlevel internal security official. This was also when he married his maternal cousin, Sajidah Khayr Allah Tilfah. Qassem's downfall was apparently not the exclusive result of his mistake of denying the Communists weapons, nor of the Baath Party's talent for staging coups. According to reliable sources, the coup was supported, if not actually engineered, by the U.S. Central Intelligence Agency (CIA). Starting in 1959, the CIA identified Qassem as a sworn enemy of the United States and a staunch ally of the Soviet Union. Over this issue there were deep disagreements between the CIA and the Mossad, the Israeli intelligence agency. The Israeli analysts were convinced that Qassem was not a Communist, nor a Soviet satellite, and they had sufficient evidence that he was not an enemy of Israel. In fact, his rivalry with Nasser served Israel's purpose of separating Iraq from Egypt. In 1963 the CIA, if it was indeed involved, had the upper hand. The Baath regime under General Abdul Salam Arif (1920–1966) as a titular figurehead launched a bloody campaign against Iraqi Communists who, despite deep reservations, had supported Qassem. Within six months the regime managed to slaughter around ten thousand men, real or perceived Communists. This, however, was no victory for the United States, because the Baath regime was still seeking Soviet, not American, support.

During the nine months of Baath rule (February to November 1963), Hussein aligned himself with the centrist faction in the party that was also supported by Aflaq. Hussein found it easy to join this faction because the group's leader, General Ahmad Hasan al-Bakr (1914–1982), the prime minister under General Arif, was his distant relative and a childhood friend of Hussein's uncle. All three were members of the Albu Nasir tribe, al-Beigat section, and all originated from the Tikrit area. This connection to Bakr proved a crucial step in Hussein's rise to power.

In November 1963 Arif and the army, with the help of some Baath officers including Bakr, toppled the civilian Baath regime and took full control of the country. After a few months of collaboration with Arif, the Baath leaders, including Hussein and Bakr, were hunted down and imprisoned. In 1964 Hussein escaped from prison. Other party members were released, which enabled them in July 1968 to stage another coup and topple the Arif regime.

**HUSSEIN BECOMES DICTATOR OF IRAQ**

There are claims that the second Baath coup was also supported by the CIA, but these claims are less credible than those regarding the 1963 takeover. Whatever the case, the July 1968 “revolution” was almost bloodless, and Arif was sent abroad. Before the coup, Hussein had been deputy secretary-general of the Iraqi “Command” of the (clandestine) Baath Party and in charge of its internal security system. By August 1968 Hussein was already the czar of domestic security. Despite his young age and minimal period of party affiliation, Hussein quickly became the power behind President Bakr. Hussein surrounded the regime's luminaries and the senior command of the armed forces with bodyguards and internal security apparatchiks who hailed from his own town and tribe. Before they realized it, the party leaders and army officers alike, including President Bakr, became prisoners in golden cages.

In November 1969 Hussein became vice president and deputy chairman of the powerful Revolutionary Command Council. At first his internal security apparatuses destroyed the party's real and perceived enemies: Communists, radical Islamists, Nasserists, pro-Western politicians, and pro-Syrian officers; and they even hanged in a public square helpless young Jews to demonstrate their Iraqi and Arab patriotism. The next step, however, was to gradually eliminate Hussein's personal rivals within the party. On July 16, 1979, Hussein replaced Bakr as president. A few days later, he purged all those in the party and armed forces whom he considered a threat. Hundreds were shot by firing squads, and Hussein became an absolute dictator.
Upon taking power in 1968, the Baath Party adopted the most extreme and recalcitrant pan-Arab, anti-Israeli, and anti-imperialist (or anti-American) rhetoric and, to an extent, practice. They launched vitriolic attacks against all the Arab regimes, but mainly those that lost the Six-Day War against Israel in 1967. Animosity with Baathist Syria became a cornerstone in Baghdad’s regional policy. Iraq promised to wage war for the liberation of Palestine and the annihilation of Israel within a year. Iraq also kept some twenty thousand soldiers in Jordan and Syria. Their slogan “everything for the [Palestine] battle” reflected their view that Iraq should be ready to sacrifice everything for the pan-Arab cause of liberating Palestine, from the Jordan River to the Mediterranean. This position changed dramatically during “Black September” of 1970. Rather than keeping their promise to help the Palestinian armed organizations to topple the Hashemite regime, Iraq’s Baath leaders ordered the Palestinian forces in Jordan to stay put, and by July 1971 the last Iraqi soldier was withdrawn from Jordan and Syria.

PAN-ARABISM, OIL, AND THE POLICE STATE

During the next decade, Hussein was the driving force behind an about-face in the Baghdad-based Baath Party’s definition of Pan-Arabism. From expressed readiness to sacrifice Iraq on the altar of the supreme pan-Arab causes, he steered party ideology and politics toward an Iraq-centered approach. He promised that Iraq would still liberate Palestine and unite all the Arabs, but only after it became all-powerful, and this could take a decade or two.

During the early 1970s, Hussein embarked on a secret military nuclear program. Detaching Iraq from the day-to-day struggle against Israel (with the brief exception of the 1973 Arab-Israeli War) did not change the rhetoric of the regime. With some exceptions due to overpowering political constraints, Israel and the United States served Hussein as reliable hate objects, matched only by Iran after 1980. By blaming on these three countries all the travails of the Arabs and Muslims, and by promising to rid the Arab world of U.S. influence and Israeli existence, Hussein’s regime sought to gain support and legitimacy among the Shia, as well as in the broader Arab and Islamic worlds.

In the 1970s the concept of Arab unity, too, underwent a metamorphosis. Traditional Ba’thist doctrine was egalitarian in that it perceived all Arab states as equal, and integrative in that it visualized the united Arab world as an amalgam in which all the existing Arab states and peoples would melt together in a huge crucible. Hussein’s Pan-Arabism, in contrast, was Iraq-centered and hegemonic. The Iraqi people and state were never to melt and disappear, and Arab unity was conceived as a large brotherly federation of Arab states and peoples, rather than a crucible. Iraq was the elder brother in the Arab family, destined to lead. By late 1978 this approach was fully formulated, and on the eve of the Gulf War of 1991, the party leadership defined the Iraqis as “the pearl of the Arab crown.” The Iraqi people were seen as having a glorious future largely because they had a glorious past. History, Hussein and his intellectuals pointed out, began in Sumer some six thousand years ago, and the modern Iraqis are the contemporary cultural heirs and genetic offspring of the glory that was Mesopotamia.

This policy represented a very secular aspect of the Baath regime. At the same time, the party also introduced its version of socialism: They took more land from large landowners and gave it to more peasants than did their predecessors; they created many agricultural cooperatives in the countryside; they nationalized more institutions; and they increased substantially government spending on social projects and development. In the mid- to late 1970s, the country experienced a thrust in the development of infrastructure, industry, social security, and health and education services, and Iraqis saw a general rise in their standard of living. In that respect, Hussein’s June 1972 decision to nationalize the property of the Iraq Petroleum (Oil) Company proved a brilliant gamble: When oil prices went up in 1973 as a result of the Arab oil embargo against the West, Iraq did not participate in the embargo and its revenues quadrupled by 1975. This enabled the regime to spend huge resources on its social and economic programs.

At the same time, the regime also allowed the creation of a large stratum of new millionaires, consisting of regime luminaries and private entrepreneurs who thrived as a result of patron-client relations with the ruling elite. This situation bred widespread corruption. Another part of the regime’s understanding of socialism was the creation of a huge body of state officialdom. This new middle class, which was dependent on state salaries and thus very docile politically, gradually replaced the original Iraqi middle class of economic entrepreneurs. Another mechanism designed for the same purpose was the encouragement of tribalism, which contradicted every tenet of the Ba’thist faith. Through the promotion of tribal shaykhs with gifts of land, money, and weapons, Hussein managed to better control the countryside. This policy was given full exposure only in the 1990s.

Above all, the 1970s and 1980s saw the mushrooming of state security apparatuses that managed to penetrate almost every corner of society. With Hussein as president, Iraq became a harsh police state characterized by severe repression of all political opponents, real and perceived. Between 1969 and 1971 and again between 1978 and 1980, the Communists were repressed, and many were
executed or disappeared in Hussein's prisons. Likewise, between 1977 and 1980, Shi'i religious activists were executed, jailed, or expelled from Iraq, and the religious universities of Najaf and Karbala were reduced to a shadow of what they had been.

**WAR WITH IRAN**

Indeed, once Ayatollah Ruhollah Khomeini (1900–1989) came to power in Tehran in 1979, the Shi'i religious threat to Hussein's regime explains to a large extent his decision to launch an offensive against Iran on September 22, 1980. Khomeini called upon the Iraqis to rise against Hussein's “infidel” regime, and with slightly more than 50 percent of Iraq's population consisting of Shia, Hussein regarded the Shia as a great threat. Considerations of balance of power and international circumstances also played a role. While Khomeini had destroyed his own armed forces through purges, the Iraqi army was well equipped and well organized. In addition, the United States had abandoned Iran completely after the hostage incident of November 1979, and it was unlikely to stop Iraq. Furthermore, after mid-1979, Iraqi-American relations began slowly to improve. When the Soviet Union invaded Afghanistan in December of that year, Hussein criticized it in no unclear terms, fearing similar Soviet support for Iraqi Communists. This common interest brought Iraq and the United States closer still.

But the straw that broke the camel’s back was a slight to Hussein's sense of pride. In April 1980 a Shi'i activist made an attempt on the life of Tariq Aziz, Hussein's closest associate. Hussein considered it an Iranian affront, and decided to go to war. Following a few months of hectic preparations on September 22, 1980, Iraq invaded Iran with eleven out of its twelve army divisions. After six days Hussein declared victory, but the war lasted for eight more years. During that war, when religious fervor proved a source of power to the Iraqi regime, many secular Iraqis, Sunni and Shia alike, returned to Islam. At first the regime tried to fight this development, but by the mid- to late 1980s, the Iranian government started to pay far more rhetorical tribute to religion than before. This rediscovery of religion was accelerated by the regime in the 1990s as it tried to harness Islam to win public support under the harsh conditions of the international embargo. During this period, Hussein initiated a faith campaign involving compulsory Qur'an classes for millions, even party members, and an increase in the number of mosques and Islamic educational institutions. Hussein himself made every effort to portray himself as a pious Muslim. Occasionally he created the impression that he had really become a devout Muslim who expected God to reward him by extricating him from the accumulating disasters in which he had landed himself. In his last meeting with his army's high command before the American invasion of March 2003 he promised them victory because, as he put it, Iraq was the only country that was guided by true Islam.

By the time the Iraq-Iran War ended in a stalemate, the Iraqi economy was devastated. Iraq entered a dangerous period of economic stagnation that Hussein knew could result in serious civil disturbances. Hussein felt that his regime was again under threat, though for different reasons than in 1980, the year Iraq's oil revenues reached an unprecedented peak. In 1980 Hussein's regime was challenged by Khomeini's mesmerizing influence on the Iraqi Shia, but in 1990 Iraq faced a major crisis of socio-economic expectations on the part of the Iraq population, which expected an economic boom after the eight-year war. Here too, there were additional incentives to go to war. Kuwait was weak militarily and the Soviet-American rivalry had ended, so an occupation of a country friendly to the United States could no longer be seen as part of the cold war. Hussein even believed that he could stay in Kuwait if he would guarantee the United States its basic needs: an undisturbed flow of oil from the Gulf at reasonable prices.

**WARS WITH THE UNITED STATES**

Hussein, however, again allowed his hurt pride to dictate a major strategic step. He saw Kuwait's overproduction of oil, and was offended by Kuwaiti reluctance to continue its financial support of Iraq and to lease to Iraq two strategic islands. Hussein interpreted these actions as expressions of ingratitude after Iraq had protected Kuwait and other Gulf states from Iran.

In this situation, as in 1980, Hussein was the incurable optimist. In 1980 he was certain that he could beat Iran and bring Khomeini down in a short blitzkrieg. In 1990 he was likewise convinced that the international community and the Arab world would, at worst, satisfy themselves with protests. Even with 500,000 American and international troops in Saudi Arabia, he still believed that the United States was bluffing, and that even if war broke out, Iraq's formidable army would stop them.

Following a ceasefire agreement with the Allied forces on February 28, 1991, that sealed Iraq's devastating defeat, a massive Shi'i revolt in the south and a Kurdish revolt in the north almost brought the regime down. The revolts were suppressed with a tremendous effort only because the United States decided to remain aloof. More than one million Kurdish refugees fled their homes for fear of a repeat of the chemical attack ordered by Hussein in 1988. The French, the British, and the United States were forced to establish for them a refuge in Iraqi Kurdistan. Hussein thus lost control over much of the Iraqi north. Iraq thereafter entered into years of weapons
inspections and a devastating phase of international sanctions that lasted until 2003.

Following the terrorist attacks in the United States on September 11, 2001, the U.S. approach to “rogue states” changed radically. Hussein was so oblivious to the change that he allowed his media to gloat over the American tragedy. Again, even with 100,000 U.S. soldiers in Kuwait, he believed that President George W. Bush was bluffing when he threatened to invade Iraq. And again, Hussein was convinced that even if the Americans attacked, his army could stop them on the outskirts of Baghdad. He did not even plan for his own escape, nor did he establish safe houses in the Sunni provinces.

Hussein was captured on December 13, 2003, by American soldiers as he hid in a spider hole near the Iraqi city of Adwar, ten miles south of Tikrit, a few hundred yards from the place where he had crossed the Tigris in 1959 in his escape to Syria after the failed attempt on Qassem’s life. Following a public trial by an Iraqi court, he was found guilty of ordering the unlawful execution of 148 Shi’i inhabitants of Dujayl, a village north of Baghdad, in retaliation for an attempt on his life there in 1982.

Hybridity

A basic definition of hybrid and its derivative hybridity, provided by the Oxford English Dictionary, is that it is a noun used to describe “a thing made by combining two different elements; a mixture.” Hybrid can also be used as an adjective to describe something of “mixed character.” The word hybrid originated in the early seventeenth century and was first used regularly in the nineteenth century to describe the offspring of two plants or animals of different species (in Latin the word meant the “offspring of a tame sow and wild boar”). The term was taken up in the mid-1800s by the Victorian extreme right to describe the offspring of humans of different races—races assumed to be of different species. Hybridity was later deployed by postcolonial theorists to describe cultural forms that emerged from colonial encounters. Its more recent adoption by social scientists—particularly those interested in migration, diaspora, transnationalism, and globalization—is varied and includes debates about its usefulness as a category. These debates stem, in part, from the term’s historical usages.

During the nineteenth century, discussions about hybridity were shaped by racist assumptions about the human species. Given that a hybrid was defined as a cross between two species that should not, in theory, be able to reproduce with each other, debates about human hybrids hinged on questions of fertility and sexuality and reflected a widespread anxiety about sexual unions between different races (in particular, between blacks and whites; one early definition of hybrid is “child of a freeman and slave”). Although arguments that relied on evidence of infertility were difficult to sustain in the face of growing mixed-race populations, persistent efforts were made to fine-tune theories of biology that perpetuated ideologies of racial hierarchy and difference. Debates about hybridity took place not only in the natural sciences, but also in social sciences such as anthropology and sociology.

The subsequent use of hybridity in postcolonial studies was shaped by linguistic models that analyze culture as a process and a site of contestation. Particularly influential here has been the work of Mikhail Bakhtin, a pioneering language theorist from Russia. Bakhtin argued that culture is not a fixed entity, but rather a fluid, evolving process that is always in flux. He believed that culture is a product of the interactions between different social groups, and that it is constantly being redefined and reshaped by those interactions.

HUTCHINSON AFFAIR

SEE Franklin, Benjamin.
linguist who theorized the political effects of hybridity in language. He used hybridity to refer to the way in which language, within a single utterance, can be double- accented—that is, it can contain two styles, belief systems, or social languages. While Bakhtin contends that “organic” hybridity (or ongoing mixing) is an important feature of the evolution of all languages, he is particularly interested in “intentional” hybridity, which he describes as a politicized process whereby one voice is able to unmask another’s authorial one through a language that is double-accented.

This conceptual use of hybridity was extended by postcolonial scholars to analyze forms of resistance to colonialism. Homi Bhabha’s work has been particularly significant; he uses the term hybridity to refer to the ways in which the power that colonial discourses attempt to exercise is disrupted in and through its very attempts to deny other knowledges, the traces of which shape colonial discourse and render it inherently double-voiced. Hybridization thus describes “the ambivalence at the source of traditional discourses on authority” (Bhabha 1994, pg. 112). Bhabha’s work celebrates hybridity as subversive and as an “active moment of challenge and resistance against a dominant cultural power” (Young 1995, p. 23). By focusing on the production of meaning, postcolonial scholarship such as Bhabha’s emphasizes representation and signification, and hence concentrates on analyzing discourse. Bhabha also argues, however, that transgressions can occur in a “third space” that includes forms of interaction and cultural difference that challenge dominant and totalizing norms.

These diverse histories of hybridity in biology, linguistics, and postcolonial studies have shaped its recent adoption by social scientists as well as debates about the term’s usefulness. Scholars interested in migration, diaspora, transnationalism, and globalization have used the term to describe the identity of persons of mixed race or cultural origin or influence (such as migrants), the cultural production of “hybrid” persons (i.e., music, language, style), and/or processes of cultural mixing that shape identity formation and cultural production. Hybridity thus shares semantic terrain with terms such as creolization, syncretism, bricolage, borderland, fusion, and cosmopolitanism. Although hybridity has been used to describe a variety of phenomena, it is often mobilized with a common theoretical intent: That is, hybrid identities, cultural products, and/or practices are often seen as challenging, in novel and creative ways, essentialist norms of culture, race, and nation.

A number of criticisms have been made recently about this politicized usage of hybridity. One set of concerns flags the inherent epistemological contradictions of the term itself: For example, one critique is that the term can never be liberatory because it always implies a prior state of purity, even as it attempts to critique this idea; also, because it is shaped by organic and biological conceptions that are also heterosexist, it risks naturalizing essentialisms. Some further argue that it is an imprecise concept if one takes as axiomatic that all cultures are hybrid and that purity is a mythical construct.

A second set of critiques addresses dominant uses of hybridity. For example, some argue that it has come to delimit certain objects of inquiry in ways that elide questions of inequality. They contend that the concept is used in facile ways to impute to hybrid persons, products, and processes a politics of resistance solely based on their purported hybrid properties. A related critique is that it has been used in academia as an apoliticized celebration of difference in ways that dovetail with the capitalist project of commodifying diversity. Some also contend that hybridity has been reduced to the experience of the migrant in the metropole at the expense of understanding how broader transnational processes that lead to migrancy also impact populations who cannot travel; these scholars relatedly raise questions about who is or is not considered “hybrid” and thus fashionable to study.

More recently, many scholars are arguing that a useful way to study hybridity is by analyzing empirically how the term hybridity is used (who deploys the concept, with which kinds of understandings, from which contexts and locations, and with what effects). By doing so, we contextualize the concept (i.e., historically, geographically) rather than imputing to it an ahistoricized principle of resistance. We can thus understand the various usages to which the concept is put, its diverse modalities, and its effects, all of which can be multiple and not necessarily resistant (for example, scholars are showing how it can be tied to political projects such as nationalism and fascism).

HYPERACTIVITY

The term *activity* in regards to hyperactivity, generally refers to movement, particularly gross motor movement. Individuals’ activity levels are variable and are affected by development, daily cycles, environmental demands, and internal states. After taking into account these factors, an individual may be considered hyperactive if his or her activity level is excessive compared to others. Since activity level, like height or weight, is continuous and can be characterized by a bell curve, *hyperactivity* is a term generally used to indicate those individuals on the high end of this continuum. *Hypoactivity* signifies those individuals on the low end of this continuum. Significant hyperactivity may impair an individual’s ability to function across academic, occupational, social, and familial domains.

Multiple medical and psychological disorders are characterized by symptoms of hyperactivity. Perhaps the disorder that is most closely tied to hyperactivity is attention deficit hyperactivity disorder (ADHD). Hyperactivity, combined with impulsive symptoms, is one of the core behavioral symptom domains identified by current diagnostic nosology; inattention represents the other behavioral symptom domain. Most pediatric patients diagnosed with ADHD have hyperactive symptoms. Hyperactive symptoms of ADHD include fidgeting or squirming in one’s seat, difficulty remaining seated, running about or climbing excessively, difficulty engaging in leisure activities quietly, acting as if “driven by a motor,” and talking excessively. As exhibited by the patient with ADHD, these behaviors are purposeless. Patients are judged to have these symptoms if they exhibit these behaviors excessively compared to individuals of the same sex and age under similar circumstances.

The hyperactivity observed in patients with ADHD is generally not episodic. Several other disorders/diseases are defined by hyperactivity that is episodic or appears as discrete behavioral events. For example, Huntington’s disease is a neurodegenerative disease that affects cognition, memory, and mood. The hallmark of this disease is hyperactivity consisting of rapid, jerky motions with no clear purpose. Similarly, tic disorders (e.g., Tourette’s disorder) are characterized by repeated and involuntary bodily movements or uncontrollable vocal sounds.

Across disorders with hyperactive features, the neurological causes of hyperactivity appear to be related to the brain’s motor circuitry or dopaminergic abnormalities. The human brain has numerous functional regions, most of which are interconnected to constitute neural circuits. One neural circuit primarily involved in motor activity begins in the cerebral cortex, connects to basal ganglia, which connect to the thalamus, and finally loops to the motor cortex. Within this circuit, there are minicircuits with substantia nigra and the subthalamic nucleus. Further, there are both direct and indirect pathways that project through this circuitry. Irrespective of subcircuitry and pathways, the basal ganglia (i.e., caudate, putamen, and globus pallidus) exert a modulating effect on this neural circuit and thus affect the behavioral manifestation of movement. The basal ganglia are primarily innervated with dopaminergic neurons. Concordantly, ADHD, tic disorders, and Huntington’s disease have all been associated either morphometric abnormalities (i.e., usually reductions) or dopaminergic abnormalities in basal ganglia regions.

Hyperactivity as manifested in disorders with episodic hyperactive symptoms, such as Huntington’s or Tourette’s, can often be assessed through observation. The mere presence of tics or choreiform movements may be considered pathological. Even at low frequencies, these abnormal episodic movements are usually indicative of disease presence. The hyperactivity associated with ADHD is less well defined. Because ADHD-related hyperactivity occurs along a continuum, the assessment of presence or absence of this hyperactivity relies heavily on clinical judgment of what is a clinically significant level of hyperactive behavior. Using all available information, a clinician must decide whether the hyperactive behavior exhibited by a patient falls outside the realm of normal behavior. Commonly utilized tools for helping to make this determination are parent and teacher rating scales for pediatric patients and self- and other-report rating scales for adult patients. Several rating scales exist for assessing ADHD behaviors, including the Vanderbilt Rating Scales, the DuPaul ADHD Rating Scale, and the Conners’s Rating Scales. Ratings are scored according to several empirically derived factors. Most scales have a factor measuring hyperactivity. An individual’s scores on the hyperactivity factors can be compared to derived age and sex norms to determine the severity of hyperactive behavior.

Other methods for assessing ADHD-related hyperactivity are the use of actometers and observation.
Actometers are mechanical devices that can be worn on a patient’s limb or placed on a patient’s chair. The actometer is designed to measure movement. Actometers attached to the patient’s body can provide valuable information about cycles of movement throughout the day and night. Patient observation can be performed in a variety of formats. Most simply, a clinician can observe the ADHD patient during interviews or testing on the day of clinical evaluation. An alternative format is to have the patient engage in an analog task (e.g., perform an academic assignment) while an observer codes activity level using an observational coding system. One may increase the ecological validity of the observation procedure by observing the patient in his or her natural environment (e.g., school). Similarly, qualitative or quantitative methods could be utilized to describe the patient’s activity level.

Evidence-based treatment of ADHD-related hyperactivity can be classified into either of two treatment strategies: medication or behavioral treatment. The most frequently used class of medications that target hyperactive symptoms among patients with ADHD are the stimulants. Stimulant medications exert their effect by increasing levels of extracellular dopamine in the brain. Stimulants wield their effects quickly and effectively. Other medications, such as atomoxetine, bupropion, and tricyclic antidepressants, have also been shown to decrease hyperactivity levels in patients with ADHD. In addition, behavioral treatment has been shown to be an effective treatment for patients with ADHD. Behavioral treatments primarily consist of consequating a patient’s behavior with behavioral contingencies. Common behavioral techniques are token economies, response cost, or daily report cards. Behavioral therapy likely exerts its effect in children by increasing their awareness of their own maladaptive behavior by making environmental contingencies increasingly salient. Both medication and behavioral therapy have been shown to be effective treatments for improving hyperactivity symptoms in children with ADHD. However, medication does appear to have a more robust treatment effect when hyperactive symptomatology is used as the outcome measure.

HYPERTENSION

Hypertension (high blood pressure) is a highly prevalent and largely symptomless chronic medical condition that affects almost one in three adults living in industrialized nations. Hypertension is more prevalent among blacks than whites, with prevalence rates of black Americans among the highest in the world. Among whites, hypertension is more prevalent among males than females until age sixty-five, when females with hypertension begin to outnumber males. Among blacks, hypertension becomes more prevalent among females in comparison to males much earlier, beginning at age forty-five. Although prevalence rates of hypertension typically increase with age in industrialized countries, inhabitants of nonindustrialized countries maintain stable blood pressures across their lifespan, suggesting that lifestyle factors associated with industrialization are associated with an increased propensity for developing hypertension. Prevalence rates for hypertension among Hispanic or Latino, Asian, and Native American populations are much lower than among white and black Americans.

There are two forms of hypertension: primary (or essential) hypertension and secondary hypertension. Essential hypertension represents the vast majority of cases and is characterized by chronically elevated blood pressure of unknown origin. In contrast, secondary hypertension is characterized by elevated blood pressures caused by another physiological abnormality, such as kidney disease, endocrine disturbances, or blockage of blood circulation. Regardless of form, hypertension is associated with increased risk for a number of diseases of the cardiovascular system, including coronary heart disease, stroke, peripheral artery disease, and congestive heart failure. Hypertension is therefore the primary cause of mortality.
in more than 10 percent of deaths among whites and more than 20 percent of deaths among blacks.

DIAGNOSING HYPERTENSION

The diagnosis of hypertension is typically made by a physician during a medical evaluation in a clinic setting. As part of this evaluation, measures of blood pressure are obtained by temporarily blocking blood flow in the brachial artery (upper arm) with an occluding cuff and listening to sounds of blood pulsations, called Korotkoff sounds, as arterial flow resumes. The first sound detected is associated with the magnitude of arterial pressure during cardiac contraction and is called systolic blood pressure (SBP). The disappearance of the Korotkoff sounds that occur when blood flow returns to normal is associated with the magnitude of arterial pressure during cardiac refilling and is called diastolic blood pressure (DBP). Measures of SBP that are less than 120 millimeters of mercury (mm Hg) and DBP that are less than 80 mm Hg are considered within the normal range. SBP's and DBP's higher than these values are associated with increased risks for cardiovascular disease consequences in a linear fashion; a diagnosis of Stage 1 hypertension is assigned for patients with SBPs between 140 and 159 mm Hg or DBPs between 90 and 99 mm Hg, and a diagnosis of Stage 2 hypertension is assigned for patients with SBPs greater than 160 mm Hg or DBPs greater than 100 mm Hg.

It is well established that blood pressures measured by health care professionals in clinic settings often bear little correspondence to blood pressures that occur during daily life, creating diagnostic dilemmas for health care providers. In some cases, patients exhibit high blood pressures in the clinic but normal blood pressures in other settings, a condition called “white coat” hypertension from the presumption that these patients display physiological stress reactions while having their blood pressure measured. Another group of patients exhibits normal blood pressures in the clinic setting accompanied by elevated blood pressures throughout daily life. This condition has been termed “masked” hypertension, as both physician and patient are unaware of the elevated blood pressures unless sophisticated automated blood pressure devices, called ambulatory blood pressure monitors, are used to assess blood-pressure levels throughout a normal day. “White coat” hypertension is typically associated with lesser risk for cardiovascular disease, while “masked” hypertension is associated with risk profiles comparable to patients with untreated hypertension.

STRESS AND HYPERTENSION

It is widely recognized that an exposure to stressful life events, such as enduring natural or human-made disasters, being employed in a highly stressful job, or living in conditions of socioeconomic deprivation, is associated with increased blood pressure. However, not all persons exposed to these types of stressful events or life situations develop hypertension. This suggests that individual difference factors exist that either increase or decrease vulnerability for developing hypertension. Individual difference factors associated with a risk for hypertension can be categorized into three types: demographic and historical developmental factors, modifiable psychological or behavioral factors, and modifiable social factors.

Demographic and historical developmental variables represent risk factors that cannot be modified by the individual. For example, it is well known that hypertension runs in families, suggesting a genetic contribution. A risk for hypertension associated with one’s age, gender, or race represents other factors that are not modifiable by the individual. Specific medical conditions such as diabetes mellitus or obesity are also associated with an increased risk for hypertension.

Several modifiable lifestyle behavioral factors are associated with an increased risk for hypertension; foremost among these are physical inactivity and excessive consumption of alcohol or sodium. Three psychological characteristics have also been associated with hypertension. First, hypertensive patients often exhibit higher rates of symptoms of depression, anxiety, and anger than persons with normal blood pressure, leading researchers to hypothesize that a negative affect is associated with an increased risk for hypertension. Second, hypertensive patients have been shown to express anger less effectively than persons with normal blood pressure, either displaying more overt aggression during confrontation or suppressing the expression of anger entirely. Third, hypertensive patients exhibit higher rates of emotional defensiveness than persons with normal blood pressures, indicating that this tendency to be out of touch with their emotions may play a role in their condition.

A few modifiable social environment factors have also been implicated in establishing risk for developing hypertension. Families of hypertensive patients, for example, have been characterized as exhibiting less social skill than those of non-hypertensive patients, particularly when handling conflict. Further, as with many other chronic medical conditions, a lack of social support is strongly associated with an increased incidence of hypertension.

No single demographic, modifiable psychological, or social environmental individual difference variable explains entirely why stress leads to hypertension, suggesting that a combination of factors explains the association between stress and hypertension. For example, several individual difference variables have been hypothesized to explain the high prevalence of hypertension among black Americans. First, increased sodium retention in response
Hypertension has been observed among black Americans that some social epidemiologists believe results from adaptive physiologies of African ancestors who survived the middle passage from Africa to America. Second, the psychological construct of John Henryism, described as effortful active coping in the face of extreme adversity, has been directly associated with blood-pressure levels in some black American samples, particularly those of low socio-economic status. Finally, an exposure to the racism and discrimination that is frequently experienced by many black Americans represents a social environmental factor that has been linked to higher blood pressure. Although consistent support linking each of these three individual difference variables to hypertension is lacking, there is sufficient evidence to suggest that each affects blood-pressure levels for some black Americans and is partly involved in explaining their increased prevalence of hypertension.

The physiological mechanisms through which psychological, behavioral, and social factors influence the risk for hypertension are unknown, although the autonomic nervous system is thought to be involved. Evidence from animal studies and from prospective trials on humans has revealed that participants who exhibit exaggerated blood-pressure responses to stress are more likely to develop hypertension later in life. According to this reactivity hypothesis, psychological factors, like the experience or inappropriate expression of anger, promote the onset of hypertension only inasmuch as they result in elevated blood-pressure responses to stress, which are presumably driven by the autonomic nervous system. Based upon this hypothesis, a considerable amount of research has linked various risk factors associated with hypertension to the autonomic nervous system. For example, healthy offspring of hypertensive parents exhibit greater blood-pressure reactions to stress than offspring of non-hypertensive parents. Similarly, both overt aggression and anger suppression are associated with heightened blood-pressure reactions to stress, in contrast to the appropriate expression of anger. Although the exact pathway through which psychosocial risk factors exert their influence on blood pressure–regulating organs is still unknown, the reactivity hypothesis has provided important clues regarding how a psychological construct like suppressed anger could lead to a physiological disturbance of blood-pressure regulation.

TREATMENT OF HYPERTENSION

Because of the high prevalence and lethal consequences of hypertension, a number of interventions have been developed to lower blood pressure. The primary treatment strategy for both lowering blood pressure and reducing the risk of cardiovascular disease associated with hypertension consists of a variety of antihypertensive medications. Although the various classes of medications operate through different physiological pathways, they all are potent blood pressure–lowering agents. Unfortunately, a large number of hypertensive patients do not take their medication as prescribed, partly because the side effects can be more noticeable than the condition of hypertension itself.

Several non-pharmacological methods are known to lower blood pressure and have served as useful adjunct treatments for hypertensive patients and as primary preventive strategies for persons at risk for developing hypertension. Weight loss, typically achieved through a combination of dietary management and increased physical activity, can result in blood-pressure reductions comparable to antihypertensive medication. Sodium restriction and potassium supplementation also reduce blood pressures, particularly among patients who are sodium sensitive. Eliminating the consumption of alcohol is an effective means of lowering blood pressure among hypertensive patients who consume alcohol regularly.

Because psychological factors are linked to hypertension, the blood pressure–reducing properties of three psychological interventions have been examined: relaxation, biofeedback, and individualized stress-management programs. The magnitude of blood-pressure reductions observed with relaxation and biofeedback interventions is generally much lower than those observed with antihypertensive medication. Because stress-management approaches are individualized based upon the patient’s unique psychological profile, larger reductions in blood pressure have been observed.

Hypertension is a chronic medical condition with no single cause. By considering both pharmacologic and non-pharmacologic interventions with respect to each individual patient, effective intervention and prevention programs will help eliminate hypertension as a public health problem.

The scientific method is central to the identity of any self-described social science. Science is distinguished from nonscience not by the content or subject of study. Rather, the distinguishing characteristic of a science is the method of investigation. The scientific method relies on systematic, repeatable testing of expectations against the observed world. In their adoption of the scientific method, social sciences more closely resemble chemistry than its alchemical predecessors, which relied instead on the application of metaphysical rules to guide their work.

The physicist may use complex instruments to observe minute characteristics of subatomic particles. Similarly, the social scientist may use surveys to observe the characteristics of human behavior. The focus on observation as a method for testing expectations unites the physicist and the social scientist in their use of a common tool of the scientific method.

THE PURPOSE OF HYPOTHESES
Hypotheses are the central tool of scientific observation. Because the core method of scientific investigation is the comparison of expectations against observations of the world, scientists need to make clear statements about their expectations. A hypothesis is a concise, falsifiable statement that is subject to observational testing as part of a scientific investigation.

Scientific research generally starts with a question about the observable world. In the social sciences research questions focus on human behavior—especially behavior related to groups (e.g., communities, countries, or societies). The scientific method says nothing about the origins of these research questions (just as it says nothing about the content of the areas of research). The scientific method simply requires that a scientist state an answer to this question (the hypothesis) that can be tested with observations (hypothesis testing).

There is a bewildering array of potential research questions—and thus hypotheses—in the domain of social science. Hypotheses can focus on expectations about voting behavior, the tendency of nations to go to war, or the factors that contribute to juvenile delinquency or to decisions about where to live (among many, many other hypotheses).

The purpose of the hypothesis is to ease the task of testing an expectation with observations of the world. A good hypothesis, then, is one that is easily tested. The ease of testing contributes to a second key aspect of the scientific method: reproducibility of testing. A clearly worded hypothesis can be tested repeatedly by a scientist and, maybe more important, by other scientists (King, Keohane, and Verba 1994, pp. 28–29).

Consider the following example. A social scientist may hypothesize that smaller class sizes in secondary schools will lead to higher performance on standardized tests. Because it is easy to observe the number of students in a class and the standardized tests scores are also easily observable (though there may be questions of the validity of the test as a measure of “intelligence” or even “academic achievement”), this hypothesis is easy to test. The test itself is also easy to replicate by the original social scientist or by other investigators. The hypothesis is sufficiently clear that any observer would be able to tell whether people in the smaller classes actually performed better on standardized tests. The judgment, then, is not a product of the specific observer but is instead independent of the identity of the scientist (a subject of some controversy that is discussed in a later section).

STRATEGIES OF HYPOTHESIS TESTING—QUANTITATIVE STRATEGIES
One of the major strategies for hypothesis testing is quantitative research. The focus of this approach is on the quantification of social science concepts for purposes of comparison and hypothesis testing. For example, a social scientist might ask whether the U.S. president’s approval ratings have gone down over the past year. This could give some sense of the power the president might have in promoting his or her legislative agenda or the chances of the president’s party in an upcoming election.

The hypothesis would be the social scientist’s guess as to how the candidate will fare against the proposed opponent. A good hypothesis will be one that is well grounded...
in the available theory on elections and that is testable against observable data (in this case a survey). The hypothesis would predict whether the approval ratings of the president have gone down over the past year. It would provide a preliminary answer to the stated research question. More ambitious hypotheses that predict specific levels of support (that the president has lost 8 percent of support from the previous year) are possible, but these require highly developed theories. One can take as an example the basic hypothesis that the president’s approval rating has gone down in the past year.

Armed with a hypothesis, the scientist will conduct a survey of a sample of potential voters to test the hypothesis. The scientist cannot, or would not want to, survey all citizens of the United States. Instead, the scientist will select a small sample out of the U.S. population. The scientist might send a survey to 1,000 citizens and see whether the hypothesis is correct within this sample of voters. The results of the survey will give the scientist a sense of the president’s current approval rating for comparison to previous approval ratings (Babbie 1995, pp. 190–193).

Quantitative hypothesis testing—the comparison of numerically represented measurements for purposes of hypothesis testing—allows for some detailed comparisons. One can say, for the sake of argument, that the survey suggests 43 percent of respondents said they approved of the job the president was doing. The previous year’s survey had reported that 47 percent of respondents had said they approved. At first glance, the evidence provides support for the hypothesis.

A number of questions remain about this test of the hypothesis. To what extent is the observed dip in approval indicative of a general trend in the U.S. population? To what extent is the dip indicative of a persistent change in approval? Tools of probability and statistics provide some opportunity to address these questions. Sampling theory provides some sense of how reliable the results are that come from a sample of a larger population (Babbie 1995, pp. 195–203). Such theory helps scientists describe the range of possible values in the population given the size of the sample surveyed. One could describe the probability that the actual approval rating was 47 percent (the previous rating) while the sample happened to be skewed toward lower approval ratings. In general, the larger the sample size, the lower the probability of these sorts of discrepancies. Such theory also provides insight into whether the variation one sees is relatively permanent or just part of the inherent variability in measuring people’s approval of a public figure. It is the ability to assess these issues of sampling and fundamental uncertainty that have convinced many of the utility of quantitative hypothesis testing techniques.

STRATEGIES OF HYPOTHESIS TESTING—QUALITATIVE STRATEGIES
Many scholars pursue an alternative style of hypothesis testing. These scholars tend to be unsatisfied with the techniques of measurement for social concepts employed in many quantitative research projects. In lieu of quantitative measurements of large samples of observations, qualitative hypothesis testing involves the careful study of a smaller number of observations with detailed treatment of the context and meaning of the social concepts themselves.

A qualitative hypothesis testing strategy follows the basic procedure of hypothesis testing. The social scientist generates a hypothesis in response to a research question. The social scientist then compares his or her expectation against the observed world. The difference between the qualitative approach and the quantitative approach reviewed earlier is in the strategy for getting reliable observations of the world.

Qualitative hypothesis testing tends to focus on detailed histories and culturally sensitive accounts of the social systems that are being studied. The detail and contextual knowledge provide the qualitative hypothesis testing strategies leverage on the challenges of hypothesis testing in two ways. First, the detailed knowledge of the subjects under study allow for careful selection of cases for study. As opposed to the quantitative strategy of multiplying the number of observations to avoid the possibility of drawing the wrong lessons from a study, qualitative hypothesis testing involves carefully selecting a few observations to achieve the ideal contrast. Second, the detailed knowledge of the subjects also allows for greater attention to the measurement of variables. Proponents of qualitative research focus on the ability to really get to know the subjects as a means to understand the nuances of the proposed effects of policies (e.g., Brady and Collier 2004).

Qualitative research tends to investigate different types of hypotheses than quantitative research, though the barriers between the two have eroded somewhat since the late twentieth century. Whereas quantitative hypotheses tend to involve statements of correlation, qualitative hypotheses have tended to focus on issues of necessary and sufficient conditions. These hypotheses focus on the conditions whose presence guarantees that an effect will be present (a sufficient condition) or whose absence will guarantee that an effect will not be present (a necessary condition) (Goertz and Starr 2003).

Theda Skocpol’s (1979) research on social revolutions exemplifies this approach. In States and Social Revolutions: A Comparative Analysis of France, Russia, and China, Skocpol studies the factors that are essential to the success of peasant revolutions in a selection of countries. To study
Hypothesis, Nested

While there is debate over the relative merits of qualitative and quantitative hypothesis testing, there are also more fundamental critiques of hypotheses testing. The quantitative and qualitative hypotheses are different strategies to accomplish the same goal. In both approaches observations are compared against hypotheses about the essential nature of the social world. In the qualitative example Skocpol is testing hypotheses about the underlying nature of social revolution. This assumes that there is an underlying nature of social revolutions. Some critics of the hypothesis testing contend that there is no singular underlying nature. These authors, mostly associated with poststructuralism, argue that there is no singular structure of society about which one can generalize or that one can discover through repeated observation (for a famous statement of this argument, see Derrida 1978).

Other authors focus their criticism not on the absence of a stable world to observe, but instead on the tools that social scientists have to observe the world (assuming that such a stable world exists). These critics allege that social measurement is inherently filled with biases. Observation, these critics allege, is inseparable from the observer. If this is the case, especially given the importance of social values to humans, there is no such thing as neutral observation of the social world. The result is that all hypothesis tests are suspect. Many of these critics recommend exploring the social world through admittedly biased accounts and narratives rather than the “at-a-distance” observation implied by the typical hypothesis testing framework (Shank 2002).

tive to the hypothesis being tested where the explanatory factors being researched have no impact on the situation under consideration. When the null hypothesis is simply the testing hypothesis with one of the parameters set at any constant, then nesting exists. If, for example, a researcher was looking for factors influencing voting decisions and one of the factors chosen was birth year, the null hypothesis would be that birth year is unimportant (and that parameter would be set to zero). In this case, the hypotheses are nested because the null hypothesis is completely included within the main hypothesis.

Nested hypotheses have been around as long as scientific research. It is both logical and easy to use a null hypothesis in cases where the factor being examined simply becomes unimportant. Nested hypotheses also frequently occur in the social sciences when researchers are investigating a primary hypothesis. Sometimes researchers will also examine secondary hypotheses (dependant on the primary one) as nested hypotheses. There are, however, conditions under which nested hypotheses should only be used with caution. Nested hypotheses are sometimes used solely for ease of computation, without any underlying research basis. Before using nested hypotheses, researchers should make certain that the question being researched provides a substantive logical reason for using nesting.

A significant problem that nested models have is deviance. As the number of parameters in a model is decreased, model deviance automatically increases. In instances where there is a significant amount of nesting, the deviance can rise substantially. The difference between the deviances of two models is the basis for comparing their reliability. Therefore if there are a significant number of parameter changes, there will automatically be a bias in favor of the more complicated model, irrespective of the real accuracy increase. According to some experts in statistics, when analysis techniques such as the log-likelihood are involved, it is impossible for a nested model to have a larger maximum than the associated non-nested model.

A lesser concern is that there are different ways of nesting hypotheses. Population groupings provide an example of this. These groupings can either be superordinated, such that one group is separated out in each nesting, or divided, in which case some of the constituent groups become one nested hypothesis and the remainder become the other hypothesis. These latter subgroups are both nested with respect to the main hypothesis but not with respect to each other. This is a different situation from the former grouping condition, where each new hypothesis is nested with respect to all preceding hypotheses. In order to compare the models and their results, it is necessary to know which approach was used. In cases where nested hypotheses are not appropriate or desirable, there are a number of Bayesian, categorical, generalized linear model, and likelihood data-analysis techniques that can be used in place of the traditional hypothesis/null hypothesis framework.

Ibn Khaldún was born in Tunis in 1332 as the child of an influential and politically active family and died 1406 in Cairo. He had a traditional education, studying the Qur’an and Islamic law; later he also studied mathematics and philosophy. He held several official positions for different rulers in North Africa’s Maghreb region, but as a consequence of political changes he lost his office in Fez and moved to Andalusia, where the sultan of Granada entrusted him with diplomatic negotiations with Pedro the Cruel, the king of Castile. Eventually Ibn Khaldún quit the service of the sultan and moved back to the Maghreb, where he held several high political offices and lived with Berber tribes. During a three-year stay with one of these tribes he wrote the *Muqaddimah*, which he continued to edit for the rest of his life. In 1382 he moved to Cairo, where he spent the second part of his life, becoming a close counselor of Sultan Barquq, who appointed him professor and *qadi* (supreme judge)—an office that Ibn Khaldún lost and regained several times. Aside from his scholarly works, he is known particularly for his encounter with the Mongolian conqueror Timur (Tamerlane) in 1401 during the latter’s siege of Damascus. During their meeting Ibn Khaldún discussed the history of the Arab world with Timur before the Mongolian army razed the city of Damascus, but spared Ibn Khaldún’s life.

Ibn Khaldún’s main work is his world history *Kitāb al-‘Ibar* (Book of Examples), a several-volume history of the known world incorporating a comprehensive introduction, the *Muqaddimah*, which is considered to be a singular achievement in his time. In the *Muqaddimah* Ibn Khaldún develops the science of human civilization or culture (*‘Ilm al-‘Umr*) to describe and analyze the history of human society. The main concept he uses for this endeavor is the *‘aṣabiyya*. This term has been translated as “group feeling,” “solidarity,” “blood ties,” “esprit de corps,” and even “national spirit.” *‘Aṣabiyya* refers mainly to family ties, but Ibn Khaldún also extends its meaning to alliances and clientships. It is conceived as a vitalizing force of group cohesion enabling its bearers to exert power. The strength of the *‘aṣabiyya* plays a determining role in the rise and fall of patrimonial empires, particularly those following the reign of the caliphs (the four kings ruling after Muhammad’s death). Rural tribesmen, or bedouins, are characterized as having a strong *‘aṣabiyya*, in contrast to sophisticated urban dwellers, who have a weak *‘aṣabiyya* but highly developed crafts and sciences. In the *Muqaddimah* Ibn Khaldún distinguishes rural or tribal life (*hadāwa*) from urban or civilized life (*hadāma*), and a rural economy based on sustenance from an urban economy in which human labor generates value, serving to make profit and accumulate capital. He analyzes urban life, examining in detail how growing cities develop and manage their commerce, law, and education. Cities are the locations of a growing division of labor, producing specialized crafts that require time and resources to be learned. Having specific requirements that can only be met by urban civilizations of sufficient size, the sciences develop in larger, longer-lasting urban civilizations. Ibn Khaldún discusses sciences such as
reading and interpreting the Qur’an, jurisprudence, mathematics, medicine, natural sciences, and occult sciences. Some sciences are criticized for their lack of religious faith (e.g., Greek philosophy) or for not adhering to historical facts (e.g., astrology and alchemy). Ibn Khaldūn argues that growing sophistication leads to decadence and corruption, weakening the ‘asabiyya and making urban civilization prone to attacks and destruction by tribes with a strong ‘asabiyya. These tribes in turn will settle down and become urbanized, generating a cycle of fall and decline of civilizations that contrasts starkly with later European conceptions of progressive development.

Ibn Khaldūn’s work was repopularized by orientalists in nineteenth-century Europe. He has been regarded as a forefather of history, sociology, and political science, and his economic theory was seen as anticipating the political economic theories of both Adam Smith and Karl Marx, the former in his insistence on the importance of free markets and free trade, and both in his theory of value. In all of these disciplines there is debate about the extent to which Ibn Khaldūn directly or indirectly influenced classic European social scientists. His historical analysis was re-applied in different contexts by proponents of anticolonial movements. Accordingly, his work has been situated in many different contexts, and its interpretations range from carefully applied hermeneutics to political polemics.

### IDEAL TYPE

An *ideal type* is a methodological construct developed by German sociologist Max Weber (1864–1920). Key to his formulation of ideal types is a focus on what motivates social action. Weber believed that we can understand human action by discovering the subjective meanings actors attach to their own behavior and to the behavior of others. For Weber, subjective meanings are important in understanding the laws and regularities that create and govern social structures. It is possible to discover these regularities because uniformity of social action is widespread; actions are frequently repeated by the same individual and they correspond to the subjective meaning the actors attach to them.

An ideal type serves as a way to determine similarities as well as deviations found in empirical cases. Ideal types do not refer to moral ideals or to statistical averages; they do not describe an individual course of action, or an ideal case, but a typical one. They are analytical constructs that enable the researcher to develop hypotheses linking the types with the conditions that brought about the event, phenomena, or social structure, or with consequences that follow from its emergence. Because they are composites of all the necessary features of an act or action, these types rarely appear in real life and do not represent the only possibility for a particular course of action. In other words, ideal types do not exhaust or fully reflect concrete reality. Rather they are analytical tools that allow the researcher to find features that are common among all the varied and unique social and historical realities in order to conduct comparative analyses. Classifying types of motivated action allows us to make systematic typological distinctions, such as between types of authority, while also providing a basis for investigating historical developments.

Weber distinguishes four basic ideal types to describe motivated social action: *zweckrational, wertrational, affectual*, and *traditional*. He organizes these types of action in terms of their rationality and irrationality. *Zweckrational* action is social action in which individuals rationally choose both goals and means. *Wertrational* action is characterized by striving for a goal, which in itself may not be rational, but which is nonetheless pursued rationally. Affectual social action is grounded in the emotional state of the actor, rather than in the rational weighing of means and ends. Traditional action is guided by customary habits of thought, by reliance on “the way it’s always been done.” Weber’s concern is with modern European and North American society, where he saw behavior increasingly dominated by goal-oriented rationality, whereas earlier it tended to be motivated by tradition, affect, or value-oriented rationality.

The most understandable type, according to Weber, is *zweckrational* action because it determines rationally
organized and administered structures like bureaucracies. Bureaucratic organizations are characterized by depersonalization, routinization, predictability, and the rational calculation of costs and benefits. Using ideal types, Weber was able to argue that the characteristic form of modern institutional organizations, such as the state, the corporation, the military, and the church, is bureaucratic.

IDEALISM

In philosophy, idealism designates a variety of historical positions since Plato (c. 428–348 or 347 BCE). The general characteristics of idealism derive from its historical examples. In metaphysics, idealism stands for a general belief about the nature of reality. In epistemology, it represents the belief that only a certain kind of reality is intelligible to the human mind. In Plato, whose idealism is influenced by the pre-Socratic philosopher Parmenides (born c. 515 BCE), the metaphysical and the epistemological aspects of idealism are combined in such a way that only ideas (or Forms) are fully real and only ideas are fully intelligible (compare Plato, *Phaedo* 65A–67B, and *Republic* 506B–518D). All forms of idealism hold that intelligible structures (“ideas”) are part of the world itself rather than merely interpretations or constructs of the mind. As a result, idealist philosophers assume either a partial or a complete identity between intelligible structures and reality itself. In the most extreme case—namely, that of the Irish philosopher George Berkeley (1685–1753)—ideas and minds are said to be the only reality there is.

Furthermore, all forms of idealism hold that intelligible structures rather than matter or physical bodies constitute the foundation of reality. In this sense, idealism is opposed to materialism and physicalism in metaphysics or ontology. Idealists also generally hold that what is known or knowable about the world are ideal entities (e.g., conceptual structures, laws, principles, values) that are either inherent in things as their essence or that function as their normative archetypes. In this sense, idealism is opposed to realism in epistemology.

Among the major idealist philosophies after Plato are the rationalist idealism of Gottfried Wilhelm Leibniz (1646–1716), according to whom reality consists of infinitely many ideal entities called monads (“metaphysical atoms”); Berkeley’s empirical or psychological idealism (“to be is to be perceived”); the transcendental or critical idealism of Immanuel Kant (1724–1804), who in the *Critique of Pure Reason* (first edition, 1781) states that “the conditions of the possibility of experience in general are likewise conditions of the possibility of the objects of experience” (A 158); German idealism represented primarily by Johann Gottlieb Fichte (1762–1814), Friedrich Wilhelm Joseph Schelling (1775–1854), and Georg Wilhelm Friedrich Hegel (1770–1831); the British idealism of Thomas Hill Green (1836–1882), Francis Herbert Bradley (1846–1924), and Bernard Bosanquet (1848–1923); and the American idealism of Josiah Royce (1855–1916).

Idealism achieved its most highly developed form and its most comprehensive and ambitious expression in post-Kantian German idealism and in Hegel’s system in particular. Although insisting that he remained perfectly true to the spirit of Kant’s philosophy, Fichte made the first decisive step beyond Kant by abandoning the thing-in-itself as well as the dualism of concept and intuition in favor of a unified first principle, the absolute ego. In this way, he very much set the agenda for post-Kantian German idealism’s drive toward a holistic system based on a monistic principle. Scholarship since the 1950s has pointed out that a rivaling realist tendency with dualistic aspects continued to be an ingredient in post-Kantian idealism, as can be seen in the philosophies of the later Fichte and Schelling.

Hegel’s strict monism conceived of the totality of reality or “the absolute” as a self-determining system exhibiting the structure of a self-referential, self-conscious subject called spirit. Spirit unfolds in human history and achieves complete self-recognition in Hegel’s speculative idealism. The conceptual structure of spirit is that of the Concept or the Idea: “The Absolute is the universal and One Idea” (Hegel 1831, §213). At the heart of Hegel’s system, for which the *Phenomenology of Spirit* (1807) initially served as an introduction, is the three-part Science of Logic. In three books titled *Being* (1812), *Essence* (1813), and *The Concept* (1816), the Logic develops the categories (“thought-determinations”) that are supposed to provide the intelligible structure of spirit’s external existence as nature, subjective, objective, and absolute spirit. These
forms of spirit in externality comprise a philosophy of nature, a philosophy of mind (soul, consciousness, self-consciousness), a moral and political philosophy, and a philosophy of religion, the arts, and philosophy itself. The categories of the Logic are derived by means of the dialectical method through which concepts are shown to generate an opposite that is nonetheless also their necessary complement (e.g., no ground without a grounded) and must therefore be combined in a new concept in order to capture the whole of which they are merely a part. The dialectical process continues until an all-inclusive concept (the “absolute Idea”) is reached. Hegel claims that the categories are generated autonomously by thought itself and have objective validity. His Logic is thus an epistemology just as much as it is an ontology. According to Hegel, it replaces traditional metaphysics.

Idealism is also used to characterize basic approaches in ethics, aesthetics, social ethics, and political science, where it is referred to as practical idealism. Idealism has been criticized for being inherently teleological in that it typically focuses on the consummation of the process of cognition in an ideal state of total (self-)knowledge or in the achievement or eschatological projection of an “end of history” (both tendencies are manifest primarily in Fichte, Schelling, and Hegel). This seems to contradict the open-endedness of the process of cognition as well as that of history. The future seems either closed or predetermined. Both assumptions contradict our normal intuitions as well as scientific rationality. Idealism’s attempt to overcome dualisms such as appearance and reality, nature and spirit, mind and matter, concept and intuition has also been criticized for making the mind, self, thought, or spirit the only true reality, thus abandoning the realistic element that normally accounts for the content of knowledge. Thus in Hegel the object or “other” turns out to be the self in disguise and genuine otherness seems to have disappeared. All cognition becomes self-cognition and reality a self-manifestation of reason. A charitable reading of idealist philosophies will point out, however, that to the extent that all knowledge is mediated by concepts or acts of interpretation, an ideal element in all cognition remains an irreducible factor. Thus this criticism must be directed primarily at those idealist positions that leave no room for ontological otherness.

Identification, Racial

Racial identification occurs when individuals consider themselves to be a part of an imagined conglomerate of people who are presumed to share certain physical, cultural, intellectual, and moral traits. This identification can be made for cultural, social, legal, or political purposes, and it involves both self-identification and categorization. Self-identification is the choice individuals make when confronted with racial choices. The options usually offered in the U.S. context are white, black, Asian, and Native American. Categorization refers to the way that people are racially identified by others. Economic analysis shows that racial-identification norms arise from the simultaneous processes of self-identification, which is achieved via within-group altruism, and categorization, which is achieved via between-group altruism. The relative payoffs to social interactions are influenced by and contribute to intergroup differences in wealth and power. It is of no small import that the categories one may racially identify with or be categorized with today are a colonial invention, created to justify the enslavement of Africans and the genocide of Native Americans (see Allen 1994).

The idea of “race” involves the notion that all of the people in the world can be divided into discrete categories, based on shared physical and cultural traits. A key notion in the idea of race is that not only can inferences be made about people’s moral, intellectual, or social value on the basis of physical characteristics such as skin color or hair texture, but also that these same traits are expected to be passed down to offspring. In the United States, as Ashley Montagu points out in Man’s Most Dangerous Myth (1997), to accept the idea of race is to accept the notion that races are populations of people whose physical differences are innately linked with significant cultural and social differences, and that these innate hierarchical differences can be measured and judged. Thus, when people are asked to identify with one or more racial categories on
survey forms, they are really being asked to report where they fall within this colonial hierarchy. And when one categorizes people in this way, one is, in effect, placing them within this same hierarchy.

Although race is an invented categorization scheme, the idea that race is real and important has become hegemonic in the United States, where people have been trained to identify others by race. If people in the United States see someone and don’t know “what they are,” they often get inquisitive or begin to feel uncomfortable. As Eduardo Bonilla-Silva points out in “The Essential Social Fact of Race” (1999), race is about “what you are,” while ethnicity is about “where you are from.” Thus to be unable to racially identify others can create confusion about “what they are.”

It may be surprising that, although people seem to view racial categories as fixed and based on fact, these classifications have changed quite a bit over the course of U.S. history. In fact, the racial classifications used by the U.S. Census have changed each time the Census has been carried out. In 1880, the U.S. Census categories were: White, Black, Mulatto, Chinese, and Indian. A decade later, Quadroon, Octoroon, Japanese, Samoan, Other Asian, Other Pacific Islander, and Some Other Race were added, only to be taken out again, along with mulatto, in 1900. Mexican was added temporarily in 1930. After many changes, the Census categories used in 2000 were White; Black, African American, or Negro; American Indian or Alaska Native; Asian Indian; Chinese; Filipinos; Japanese; Korean; Vietnamese; Guamanian or Chamorro; Samoan; Other Asian; Other Pacific Islander; and Some Other Race. In addition, in 2000, people were given the option of checking off as many of these options as they wished, thereby greatly increasing the number of racial choices available to people.

Notably, people were given the opportunity to identify themselves multiracially in 2000 because of a political campaign to allow people more than one choice on Census forms. This is just one of many campaigns that have altered the ways racial classifications are used. There is also a strong movement to dissolve the use of race in public policy altogether. This has resulted in the passage of Proposition 209 in California in 1996 and the adoption of Proposition 2 in Michigan in 2006. Both of these propositions prohibit all state and local government entities from using race, ethnicity, color, gender, or national origin to make decisions about public employment, public education, or government contracting. California also witnessed another movement to remove racial and ethnic identifications from data collection efforts, in the form of Proposition 54, the Classification by Race, Ethnicity, Color and National Origin Initiative.

Following the defeat of this proposition in 2003, the American Sociological Association (ASA) issued a statement about the importance of being able to collect data on racial identifications. The ASA also published a statement in 2002 arguing that, although racial categories are socially constructed, it is important to ask people to give their racial self-identification in data collection efforts, insofar as this provides vital information about inequalities in educational, labor market, health care, and other outcomes. In other words, as long as a social meaning is given to race, it is important to know how people identify themselves racially and how this identification affects their prospects for success.

The creation of the Hispanic category was also the result of political campaigns, primarily in the 1960s. Hispanics or Latinos/as are currently the largest and fastest-growing minority group in the United States. However, according to the regulations used by the U.S. Census, Hispanic is an ethnic, not a racial category. Thus, Hispanics, just like non-Hispanics, are asked to choose between the various racial categories on the Census form. Other data collection efforts, such as those used by some educational institutions in the United States, include Hispanic as an option, although these classification schemes are often designated as racial or ethnic self-identification. Hispanic, in many ways, functions as a racialized category in the United States, insofar as people use physical cues to determine whether or not someone is Hispanic. However, the category Hispanic, like the categories Arab or Middle-Eastern, is a result of a different set of historical processes than those through which the categories White, Black, Asian, and Native American were created. European scholars writing in the seventeenth century generally restricted themselves to these latter four categories in their pseudo-scientific work on the characteristics of the human races.

Despite this tainted history, racial identification cannot be seen solely as an act of dominance, for it can also be an act of resistance. By identifying themselves racially, as opposed to ethnically, some Hispanics may be resisting white privilege and expressing solidarity with other people of color. Indeed, there is evidence that Latinos who experience discrimination are more likely to racially identify as Latino than those who have not experienced discrimination.

Racial identifications are thus social, cultural, political, and legal categories that are the result of particular historical processes, and that continue to be subject to changing ideas about the reality of race. As social categories, they are related to various social outcomes such as educational attainment and wages. As cultural categories, they are imbued with meaning and associated with certain cultural characteristics, such as language, dialect, or musi-

cal preferences. As political categories, they can be used to mobilize people behind a common agenda. And as legal categories, they have been used to prevent miscegenation, to enforce segregation, and to maintain racial slavery.

IDENTIFICATION PROBLEM

The identification problem is a deductive, logical issue that must be solved before estimating an economic model. In a demand and supply model, the equilibrium point belongs to both curves, and many presumptive curves can be drawn through such a point. We need prior information on the slopes, intercepts, and error terms to identify the true from the presumptive demand and supply curves. Such prior information will give a set of structural equations. If the equations are linear, and the error terms are normally distributed with zero mean and constant variance, then a model is formed for estimation.

A typical identification process may fix the demand curve and shift the supply curve, cutting the demand curve at many points to trace it out. By the zero mean assumption of the error term, half the observations are expected above and half below the demand curve. In the same way, the supply curve can be identified. This method originated with Ragnar Frisch (1938) and Trygve Haavelmo (1944). Tjalling Koopmans evolved the order and rank conditions for identifying linear models (1949). Franklin Fisher’s work was the first major textbook on the subject (1966), and Charles Manski extended it to the social sciences (1995).

The order condition is the most used technique for identifying a model. Each equation in the model has a predetermined variable that is either given from outside of the model (exogenous) or determined in the model (endogenous) but fitted with a lag. A standard exogenous variable for the supply curve is technology, T, and for the demand curve it is income, Y. A two-function model with Q = f(P, Y) for the demand and Q = f(P, T) for the supply, where P is price and Q is quantity, meets the order condition for identification by excluding technology from the demand curve, and by excluding income from the supply curve. The number of excluded variables is one in each equation. The order condition requires that the number of exogenous variables is less one. An equation is exactly identified if EV = M – 1, overidentified if EV > M – 1, and underidentified otherwise. In the two-function model above, the equations are exactly identified because the exogenous variables P and Q yield M = 1, and each equation has only one excluded variable, Y or T.

The rank condition guarantees that the equations can be solved. Econometric texts often create a spreadsheet to demonstrate the rank condition. For the model above, the column is labeled with the variables Q, P, Y, T, and the rows contain information on the equations. Each cell has either a 0 for an excluded variable or a 1 for an included variable. For the demand function above, the entry for the row vector is [1, 1, 1, 0] and for the supply function [1, 1, 0, 1]. To identify the demand curve for the order condition, first locate the zero in its vector, then pick up the corresponding number in the supply vector. The picked-up number, which is 1, should be equal to M = 1, which is also 1. With many equations, the numbers that we pick up will array into many rows and columns. The general rank test requires one to find M = 1 rows and M = 1 columns in that array whose elements are not all zeros, because such a (M – 1)(M – 1) spreadsheet will make the model solvable.

IDENTITIES, DEADLY

“Deadly identities” is the literal translation of the title of Amin Maalouf’s nonfiction *Les identités meurtrières* (1998), which examines the issues and problems surrounding individuals having multiple social identities. Maalouf (b. 1949) is a Lebanese-born Catholic Arab novelist who has lived in Paris since 1977, writes in French, and is the 1993 winner of the Goncourt Prize, France’s most prestigious literary award. For Maalouf, the term *identity* is a “false friend.” “It starts by reflecting a perfectly permissible aspiration, then before we know where we are it has become an instrument of war” (Maalouf [1998] 2000, p. 32). The meaning of *identity* here is that of social identity, which results from our identification with others in social groups according to shared religion, ethnicity, nationality, gender, age, occupation, place of residence, and so forth. Social identities generate violence when social groups are in conflict, and their respective members behave antagonistically toward each other, though they may have no animosity toward one another as individuals. Such conflicts have become more common in the age of globalization, Maalouf believes, because of an ever-accelerating intermingling between peoples. For many, then, the dilemma this often creates is a choice between a complete loss or a vigorous assertion of traditional identities—between the disintegration of identity and fundamentalism.

But Maalouf argues that this choice is an illusion, because people do not have just one social identity, which is then their individual identity; rather, they have many social identities, the specific combination of which gives each person a unique individual identity. This is the concept of *complex identity*, and it is not unchanging, but changes over a person’s lifetime, as do a person’s associations and experiences. Maalouf offers several interpretations of complex identity. One is the idea of a limiting concept: the “more ties” one has, the “rarer and more particular” one’s identity becomes (Maalouf 1998 [2000], p. 18). Alternatively, an individual’s complex identity develops continuously over a lifetime as new characteristics are acquired “step by step” (p. 25). The meaning, however, that most directly targets the problem of violence is complex identity as that which individuals assemble and arrange for themselves out of their different social identities (p. 16), since this presupposes a capacity for reflection about one’s social identities, which Maalouf sees as the best protection against the insanity of murder and butchery in the name of some “tribal” identity.

In this respect, Maalouf is close in his thinking to that of the 1998 Nobel laureate in economics, Amartya Sen (2006), who has also argued that individuals can appreciate their identities rather than be captives of them. Both writers, then, closely associate individual identity with this reflective capacity. Their understanding of what it means to be an individual contrasts with the view in much of social science that takes individuals to be unconsciously responsive to a variety of motives, drives, and desires.

IDENTITY

Identity is a pervasive concept in popular culture. Broadly speaking, *identity* refers to the overall character or personality of an individual or group. For example, a young mother might define her identity as that which reflects the essence of who she is (such as being a woman, spouse, and parent) and how she got to be that way. A business can have its own identity, perhaps defined by its unique corporate culture or its advertising history. Significant historical events like wars, natural disasters, or surges in immigration can play important roles in helping to define a nation’s identity.

On the one hand, the defining features of identity frequently entail elements that must be “found” by an
Identity

individual or group. For example, a musical group or the cast of a television show might have to work together for a long period of time before its performances flow smoothly and effortlessly and it is able to establish its own voice or overall character. Adolescents as well as adults can pass through identity crises that refer to periods of personal uncertainty or confusion. When a sports coach talks about his or her team finding its identity, this may refer to the development or recognition of a consistent way of playing or performing.

On the other hand, individuals or groups can also “lose” their identity through a variety of events or circumstances. For example, when politicians, celebrities, or other public figures engage in controversial behavior, those individuals must frequently work to reclaim or redefine their identities. A company that has made poor business decisions might be referred to as having lost its corporate identity. The modern phenomenon of identity theft is another example of identity loss, although it is more accurate to refer to this phenomenon as identification or ID theft. The popularity of the identity theft label suggests that an important part of lay definitions of individual identities are the public, demographic, and commercial means of identification.

As the previous examples illustrate, the popular boundaries of the identity concept are quite broad. This concept is similarly pervasive and broad in the theories and research of the social sciences and humanities. Self and identity are frequently used interchangeably by such theorists and researchers. In fact, sometimes writers will combine the terms into concepts such as self-identity or ego-identity. Within the social sciences and humanities, different disciplines emphasize different components of the concept. Thus, it is useful to consider how different fields define and operationalize identity.

Social science theorists and researchers distinguish a large number of different kinds of identity. Examples of identity types include racial, ethnic, group, social, religious, occupational, gender and sex role, cultural, physical and bodily, musical, athletic, academic, and so forth. Among these different identity types, a common distinction is made between personal and social identities. Personal identity usually refers to the unique characteristics of a person, including personality traits, personal values, opinions and preferences, physical characteristics, and career and lifestyle choices. In other words, these refer to aspects of a person’s identity that are distinct and different from other people. Social identity usually refers to one’s social roles, such as gender, racial, religious, political, ideological, and national group memberships. Typically, these roles involve ways that a person’s identity is similar to others, such as sharing a physical characteristic, speaking a common language, having a similar social class or socioeconomic status, practicing the same religion, or living in a common region.

Regardless of whether one focuses on personal or social facets, identity development involves a sense of sameness, continuity, and unity. Philosophically speaking, personal identity refers to the extent that an individual’s characteristics are the same over time. That is, identity establishes the conditions that define a person’s stable uniqueness. This can refer to the physical, psychological, and social aspects of the person. Thus, most social scientists agree that identity is something that develops over time and requires organization and integration, often achieved through the resolution of personal or social conflicts or crises. The failure to achieve some degree of identity coherence is thought to be a symptom of psychological, social, or cultural problems.

Identity also entails an individual commitment to a set of values and goals associated with specific characteristics. For example, much of personal identity involves identifying one’s unique features and determining the value of those features and how they relate to a person’s short-term and long-term goals. Social identity supposes an awareness of one’s group memberships, as well as some level of commitment, closeness, or emotional attachment to those groups. People who highly value their social identities are more likely to act in ways that are consistent with those roles than people who do not value their social identities. Identity development is, therefore, tied to how people think about themselves and how they decide which aspects of their experience are most important as they define themselves. In other words, the development of identity involves personal and social processes of definition, construction, and negotiation.

HISTORY OF THE IDENTITY CONCEPT

The pervasiveness of identity-related concerns is a relatively recent cultural and historical phenomenon. The psychologist Roy Baumeister (1986) described several influential social trends in European and American societies running from about 1500 to 1800. During these centuries, a variety of social, cultural, and economic changes corresponded with a shift in how philosophers, artists, writers, and the lay public viewed personhood and identity. Since the Middle Ages, there has been a weakening of the importance of a person’s geographical home and of the institutions of marriage and job in defining one’s identity. At the same time, the formerly important roles of one’s family of ancestry, social rank, gender, and religion have been at least somewhat trivialized. Thus, traditions and institutions that had previously defined people’s identity lost importance and influence.
These changes corresponded with new views on what constituted a person’s identity. For example, people began to consider the possibility that there is a hidden self; that individuality is important; that there is a separation of their public, social lives from their private lives; and that children develop and have their own potentialities worthy of attention. In other words, the boundaries of identity became increasingly broad and malleable. Baumeister (1986) argued that these trends continued through the twentieth century, reflecting an age of mass consumption, greater occupational choices, dramatic technological changes, and the marketing of both products and people. The net effect of these social, cultural, and economic changes is that people in industrialized societies are now plagued with difficulties in defining their identities. Because of the loss of traditional ways of knowing who one is, the more abstract, elusive sense of identity makes it increasingly difficult to define. Much more than was the case one hundred or two hundred years ago, people must work to find or uncover who they are, in order to resolve the dilemmas of modern personhood.

Contemporary identity requires choice, achievement, and frequent self-redefinitions as opposed to the passive assignment of identity of the past. With the widespread desire for establishing and determining one’s individuality and uniqueness comes greater difficulty, choice, and effort in achieving this. For instance, modern identity can be constructed out of one’s personality traits, material possessions, personal accomplishments, group memberships, and activities and organizations. For these reasons, various writers have labeled identity as “empty,” “saturated,” and “overburdened,” and as reflecting “an epidemic of role distance” (Hoyle et al. 1999, p. 49). Some writers argue that European and American culture’s extreme preoccupation with an inner, independent identity leads to a devaluing or ignoring of the social world and the potential negative effects of contemporary social arrangements. This causes a seeking out of experiences and material possessions in order to avoid feelings of worthlessness or identity confusion.

TREATMENTS OF IDENTITY IN THE SOCIAL SCIENCES

Identity is a topic of extensive theory and research for many of the social sciences. Two disciplines that have devoted a great deal of attention to identity are sociology and psychology. Sociologists generally define the overall self as consisting of multiple identities tied to the different roles a person plays in the social world. Early twentieth-century sociologists such as Charles Horton Cooley (1864–1929) and George Herbert Mead (1863–1931) emphasized how other people provide “reflected appraisals” that encourage the understanding and establishment of a sense of identity. In his 1959 book The Presentation of Self in Everyday Life, the sociologist Erving Goffman (1922–1982) brought a dramaturgical approach to social identity. Goffman theorized that people play social roles like actors on a stage, claiming and becoming committed to a particular public or group identity. Part of this identity includes a public “face” that a person claims and then defends in social interaction. In later writings, Goffman presented the idea of a “spoiled” identity, in which a person can be stigmatized as a result of deviant behaviors or personal characteristics.

More recently, the symbolic interactionist perspective has assumed a prominent role in the sociological approach to identity. Contemporary versions of symbolic interactionism examine how a person’s identity is affected by the elements of social structure, in particular the social positions or roles that one plays and the meanings and expectations associated with those roles (Stets and Burke 2003). Role identities may differ in number, prominence, salience, and value to an individual, and sociologists have conducted a great deal of research on these aspects of role identity. For example, a greater number of role identities have been associated with greater resistance to stress and more positive mental health, particularly when those identities are voluntary or freely chosen ones rather than when they are conferred or obligatory.

The meaning of a role identity is something that a person must determine and negotiate. As such, it can be affected by the reactions of others. Over time, there can be changes in a role, as well as in the identity associated with that role. For example, when a person takes on a new role of being a spouse in a married couple, specific behaviors associated with that role must be defined and may change over time. In addition, the definition and boundaries of the spouse identity can change. Thus, the taking on, development, internalization, and changing of multiple roles comprise the most important features of identity from a sociological perspective.

Within psychology, the best-known treatment of identity comes from Erik Erikson’s (1902–1994) psychosocial stages of development across the lifespan (Erikson 1968). When and how does a coherent sense of identity develop? Research suggests that identity concerns are especially prominent among late adolescents and early adults. This seems to be due to the fact that it is only by this time that young people become physically and sexually mature, are competent in abstract thought, show increased emotional stability, and have a certain amount of freedom from parental and peer constraints. Younger children are typically not assumed to have an identity (at least in the overall coherent and stable sense of the term). However, aspects of identity (e.g., age, sex, and race) have been shown to be important to the self-perceptions and
Understanding how a person is similar to and different from others is an important part of identity formation. In this regard, significant others can help to define the developing sense of identity.

In Erikson’s theory, adolescence is a time of increased power and responsibility and also a time when young adults must determine who they are and where they fit into their culture and society. Thus, the struggle for a sense of identity and the formation of a “philosophy of life” seems to be especially intense during this period. There are several different ways that young adults might deal with their identity struggles (Marcia 1980). For example, a person might show identity foreclosure. This can occur when people prematurely commit to and unquestioningly adopt the beliefs, values, or roles prescribed by parents rather than going through the process of developing their own beliefs, values, and career choices. Second, people may delay commitment in order to try out alternative identities, beliefs, roles, or behaviors. In this situation, called an identity moratorium, such people are actively caught up in the throes of the identity struggle and are striving to resolve it. However, they have yet to develop a coherent and stable identity.

A third possible outcome of the young adulthood identity crisis is called identity diffusion. This refers to an unwillingness to confront the challenge of charting a life course and a failure to achieve a stable and integrated sense of self. Unlike in the moratorium, such people show little concern or effort to resolve their self-doubt, apathy, and passivity. Finally, people can arrive at a sense of self and direction and form an integrated image of themselves as unique persons. This is called identity achievement. Such individuals have passed successfully through the identity crisis and are now able to make a commitment to a career objective and a personally meaningful set of beliefs and values. For Erikson and other identity theorists, adequate identity formation is the foundation of sound psychological health in adulthood. Identity confusion can interfere with important developmental transitions during the adult years.

More recent psychological approaches to identity include the idea that self-narratives or life stories serve as central features in the creation of a person’s identity. Psychological research also shows that people engage in a wide variety of behaviors to construct, test, and confirm their identities. For example, social psychologists have studied the processes by which people present specific identity aspects to others and manage the impressions that others form of them. What makes particular identity characteristics salient is likely to be tied to the social setting or context. Psychologists are also interested in studying how organized cognitive structures (or schemata) serve to maintain a person’s identity. For instance, cognitive structures can filter out competing or inconsistent information or lead to other forms of biased information processing that serves to protect or maintain one’s identity.

Whereas sociologically based identity theories focus more on the different roles that constitute a person’s identity, psychologically based social identity theory deals with how membership in groups is associated with self-categorization and social identities. For example, those who belong to the same group are seen as ingroup members, whereas nonmembers or those who belong to different groups are seen as outgroup members. A large amount of research has shown that such ingroup-outgroup categorization (sometimes based on arbitrarily defined group membership) results in ingroup favoritism and outgroup discrimination. Thus, it appears that merely belonging to a group can create meaningful social identities with strong attitudinal (e.g., prejudice) and behavioral (e.g., discrimination) implications.

Other disciplines within the social sciences and humanities also have utilized the identity concept in their theories and research. For example, political scientists are interested in the role of identity as a source of people’s political beliefs or political party affiliation. They are also interested in how identity is affected by isolation, alienation, anomie, and social injustices in modern society and how these problems impact social structure, political party affiliation, political action, and international relations. As such, the identity concept is one of many factors that can affect political actions and larger social conflicts.

Political scientists sometimes focus on how membership in particular groups is associated with a specific identity that may have implications for social movements, community mobilization, and other forms of collective behavior. That is, through the identification or construction of a collective identity, groups may be able to increase pride and consciousness, mobilize resources, and bring about societal changes. In other words, groups may strive to expand the range of a particular identity characteristic into a political force with accompanying social and legislative reforms. This process is referred to as identity politics. Examples of identities that fall into this category include religion, race, ethnicity, gender, and physical disability. Critics have argued that politicizing an identity component can be counterproductive to the goal of social change. For example, by calling attention to a specific identity, a group may find it more difficult to address the social injustices associated with it. Or there may be broader social or cultural backlashes directed toward a group identity.

Anthropologists and other social scientists have explored the processes of cultural identification and cultural variations in identity construction. A popular dis-
tinction relates to identity differences that are based on independent (or individualistic) and interdependent (or collectivistic) cultural construals. Educational researchers consider the development of academic identity and the relationship of various identity facets to academic achievement. Business and marketing researchers examine the mechanisms and processes associated with developing a corporate or brand identity in consumers. Within the humanities, a great deal of attention has been devoted to cultural and historical trends in the construction and management of identity (e.g., identity politics) and how identity is represented in and affected by works of art, music, theater, and literature.

Some of the current issues related to the identity concept include how to best measure the different kinds of identities and how multiple identities (and conflicts among these) affect behavior in specific situations. In addition, the development of different kinds of identities and how they interrelate from childhood through adulthood has received little research attention. How do multiple identities overlap and affect individual and group behavior? This is a particularly important question when considering broad social, cultural, or nationalistic actions, where several different identities may combine or conflict. For example, adopted or biracial children may experience unique issues as they attempt to develop their racial or cultural identity. More broadly speaking, one of the effects of an increasingly multicultural world is that the establishment of one’s identity may become more difficult or complicated. One interesting domain for identity theorists and researchers concerns how technological changes, particularly those associated with the Internet, affect identity processes. For example, the social scientist Sherry Turkle (1995) has shown that exploration of new, alternative, and multiple identities has become significantly easier and more varied through online communities, multiuser domains, role-playing games, and fantasy worlds.

In summary, identity is a very broad and influential concept in the social sciences and humanities. It has proven to be remarkably fluid and malleable, with different disciplines able to define identity in ways that best suit their purposes and emphases. The cultural and historical trends that led to changes in identity over the past several centuries are likely to continue to provide new challenges to identity formation in the future. Increasing globalization, industrial development, scientific advances, and technological innovations will mean that difficulties in defining identity will be a worldwide phenomenon.

IDENTITY, SOCIAL

Social identity is defined as an individual’s identification with others. In contrast, the concept of personal identity can be understood as an individual’s identity apart from others. At the same time, social identity and personal identity are clearly related. Furthermore, whereas individuals are usually thought to have a single personal identity, they have many social identities associated with the many different collections of other individuals with whom they identify. These different collections of other individuals are usually thought of as social groups, though there are different ways to understand the idea of a social group, explain its boundaries, and account for the attachment individuals have to social groups. For example, individuals might identify with others by race, gender, nationality, and religion (very large social groups or social categories), with those in their workplaces and communities (intermediate size social groups), and with friends and family members (small social groups). In all cases, social identity provides a social basis for how individuals see themselves—a sense of self or self-image—that depends on their seeing themselves as being much like a reflection of those others with whom they identify.

There are two broad approaches to understanding social identity: the social identity approach (particularly in
the form of self-categorization theory) and the sociological approach to identity (Hogg, Terry, and White 1995). The social identity approach derives principally from the work of Henri Tajfel and John Turner, who explain social identity in terms of the individual’s knowledge that he or she belongs to certain social groups, combined with the emotional and value significance this membership imparts. Self-categorization theory concerns the cognitive processes by which individuals come to identify with others and embrace membership in social groups. In experimental research, individuals exhibit in-group favoritism and out-group biases for arbitrarily constructed social identities. This can be understood as an “accentuation effect” of group membership, whereby once individuals believe a particular social category applies to them, they perceptually “accentuate” both the similarities among stimuli falling within that category and the differences between stimuli from that and other categories (Tajfel 1959). Tajfel argued that the accentuation effect helps explain such phenomena as stereotyping, prejudice, and ethnocentrism.

The sociological approach to identity derives from the symbolic interactionist thinking of George Mead, and assumes there to be a reciprocal relation between the self and society or between the self and individuals’ social identities (Stryker 1980). Social groups are seen as being structured in terms of different roles, and individuals accordingly have different types of relationships to social groups depending on the roles they occupy in those groups (Stets and Burke 2000). Roles can be paired with counter-roles (such as parent and child), or in more complicated group and institutional settings (such as in business firms) where roles are more highly differentiated, they can exhibit a variety of interconnections with one another. On the assumption that there is a reciprocal relation between the self and society, roles are subject to interpretation and negotiation, while at the same time individuals generally seek to match their own self-conceptions or self-images with social expectations of their roles. Thus, whereas social identity theory focuses on in-group and out-group relationships with respect to particular social groups, the sociological approach focuses on how individuals’ social identity relationships are structured and negotiated within social groups.

Neither the social identity approach nor the sociological approach to identity pays significant attention to the relationship between social identity and personal identity. Yet the meaning of social identity as “identification with others” implies that there is a separate someone who identifies with others, and thus that individuals have an identity apart from or over and above their social identification with others. Also, the idea that an individual has many social identities implies some concept of personal identity, if only because it assumes the existence of a single subject to whom those multiple identities belong. Thus, the concepts of social identity and personal identity are related to one another, and need ultimately to be explained jointly to give a full understanding of either concept. Unfortunately, little has been done to develop this more comprehensive kind of explanation.

IDENTITY CRISIS

“Identity versus Identity Confusion” is the fifth of Erik Erikson’s eight psychosocial stages of development, which he developed in the late 1950s. Adolescence is the most salient time for defining identity, the process of determining the meaning, purpose, and direction of one’s inner, unique core of self—while also maintaining some sense of sameness and continuity with one’s past and of comfort within the context of one’s culture. An identity crisis is “a necessary turning point, a crucial moment, when development must move one way or another, marshaling resources of growth, recovery, and further differentiation” (Erikson 1968, p. 16). The most common use of the term identity crisis refers to normative psychosocial development during the periods of adolescence and emerging adulthood. This concept of crisis, however, has been applied quite broadly, at times being used to include not only healthy individual growth but also other issues of individual therapy and reconsiderations of what it means to be part of a reconstituted nation in the process of rapid historical change.
Based on Erikson’s epigenetic principle, each of the other seven psychosocial stages has implications for the quality of identity resolution. Along a continuum within each stage, a person will express healthier psychosocial development if that stage’s crisis is resolved with more positive (syntonic) outcomes. Ideally, for example, one develops reasonable trust in the world, autonomy, initiative, efficacy, identity, interpersonal desire, worth, and finally with stage eight, satisfaction. The results of ego syntonic or dystonic outcomes may include viewing one’s self as either protected or vulnerable in the world, self-controlled or disordered and dependent, ambitious or evasive, competent or incapable at tasks, committed or lacking conviction, loving or reclusive, productive and caring or not valued, and a success or a failure. Unsatisfactory aspects of one’s identity in these areas (i.e., being more dystonic) may lead to crisis, in which one must rework a previous stage and seek a different outcome.

James Marcia has provided the most influential empirical framework for identity formation. He has focused on a behavioral expression of identity by investigating the processes of exploration of alternatives and commitment to values, beliefs, and goals in various life domains, such as career and ideologies. From the dimensions of exploration and commitment, he derived four identity statuses: Achievement (exploration resulting in commitment), Moratorium (present exploration with the intention of achieving a commitment), Foreclosure (ascribed commitment with no exploration), and Diffusion (no commitment whether exploration has taken place in the past or not). Moratorium is the status of “crisis” or exploration, defined by the need to arrive at a self-definition, which is actively propelled by the individual.

In 1990 Alan Waterman described an important goal of identity exploration as the identification of potential talents, the development of which can lead to feelings of personal expressiveness. It is the responsibility of significant others to aid the individual in learning the process of exploration and to provide information that may help the individual to arrive at a commitment that is exemplified by continuity, “goodness of fit” within self, and appropriateness within one’s social contexts. While each individual should find unique domains of importance, individuals identified as being in a state of long-term Diffusion, without meaningful self-definition in any domains of significance, may be perceived especially as being in need of counseling. These individuals approach the task of identity with passivity or perhaps apathy, and they have poor resolution of at least some of the other psychosocial stages of development.

Working within Erikson’s psychosocial theoretical perspective, decades of research have emerged from Marcia’s empirical framework focused on development in numerous and varied contexts (e.g., Marcia 1966; Kroger 2007). Examples of other contemporary approaches to identity and its measurement include the structural stage perspective, which focuses on the roles and status granted by one’s society. These and other frameworks are described and critiqued by Jane Kroger in Identity Development: Adolescence through Adulthood (2007).

Mixed societal demands are particularly problematic for identity formation and its refinement at a time when one is seeking continuity or looking to find a sense of one’s uniqueness yet still fit within one’s societal parameters over time. In those instances in which one is part of a minority (e.g., by race, ethnicity, or sexual orientation), or if one has identifications with multiple groups (e.g., by being biracial), or if one is pulled by conflicting messages (e.g., those coming from the media and the family), an identity crisis is likely to emerge. Respect for diversity of self would go a long way in allowing people to be “uniquely themselves” while belonging to a community. Healthy “crisis” or exploration can afford people the opportunity to knowledgeably investigate choices in which there is positive meaning with regard to where they have come from, where they presently exist, and where they envision their future to be.

IDENTITY MATRIX

The identity matrix $I_n$ is an $n \times n$ matrix with 1s along the main diagonal and 0s in the off-diagonal elements. It
**Ideology**

can be written as \( I_n = \text{diag}(1, 1, \ldots, 1) \). For instance, for \( n = 3 \), the matrix looks like

\[
I_3 = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix} = \text{diag}(1,1,1)
\]

The columns of the identity matrix are known as the unit vectors. For the above example, these are \( e_1 = (1 0 0)' \), \( e_2 = (0 1 0)' \), and \( e_3 = (0 0 1)' \). If the dimension of the matrix is \( 1 \times 1 \), the matrix reduces to the scalar 1.

The identity matrix has the following properties:

1. It is square, that is, it has the same number of rows and columns.
2. It is symmetric, that is, transposing rows with columns (or vice versa) we obtain the matrix itself, that is, \( I = I' \) where \( I' \) is the transpose matrix.
3. It is idempotent, that is, \( I^2 = I \); in the scalar case this is equivalent to \( I^2 = 1 \).
4. For any \( n \times n \) matrix \( A \), multiplication by the identity matrix delivers the matrix \( A \) itself, that is, \( AI = A \); in the scalar case this is equivalent to \( a \times 1 = a \).
5. It has the commutative property, that is, for any \( n \times n \) matrix \( A, AI = IA = A \); in the scalar case, this is equivalent to \( a \times 1 = 1 \times a = a \).
6. For any nonsingular \( n \times n \) matrix \( A \), there exists a matrix \( A^{-1} \) such that \( AA^{-1} = A^{-1}A = I \) where \( A^{-1} \) is called the inverse matrix of \( A \). In the scalar case, this property is equivalent to the inverse operation of multiplication (or division), that is, \( a \times \frac{1}{a} = \frac{1}{a} \times a = 1 \).
7. It has full rank; the \( n \) columns (or the \( n \) rows) of the matrix are linearly independent vectors and consequently the determinant is different from zero. The only symmetric, idempotent, and full rank matrix is the identity matrix.
8. Because \( I \) is a diagonal matrix, its determinant is equal to the product of the elements in the main diagonal, which in this case is equal to 1 regardless of the dimension of the matrix. A positive determinant is a necessary and sufficient condition for the identity matrix to be a positive definite matrix. The trace of the identity matrix is \( \text{tr} I_n = n \), which is the sum of the elements in the main diagonal.
9. The \( n \) eigenvectors of the identity matrix are the unit vectors, and all the \( n \) eigenvalues are equal to 1.

Matrix algebra is a fundamental tool for the econometric analysis of general regression models. Classical estimation methodologies such as Ordinary Least Squares (OLS), Nonlinear Least Squares, Generalized Least Squares, Maximum Likelihood, and the Method of Moments rely on matrix algebra to derive their estimators and their properties in an elegant and compact format. The identity matrix shows up in several technical proofs. For instance, the identity matrix is an integral part of a projection matrix. In the OLS regression of \( y \) on \( X \) with a sample of size \( n \), the projection matrix is \( P \equiv (I_n - X(X'X)^{-1}X') \). It is important because when \( P \) is applied to a vector such as \( y \), the result is the fitted values of \( y \) through the regression, that is, \( \hat{y} = Py \).

**IDEOLOGY**

The previous edition of this *Encyclopedia* contains two entries devoted to *Ideology*, one on its concept and function by Edward Shils, the other on “Ideology and the Social System” by Harry M. Johnson, which taken together well illustrate the difficulties involved in achieving a common understanding of the term’s meaning. Shils’s contribution is quite stipulative and opinionated. After distinguishing ideologies from “outlooks and creeds, systems and movements of thought, and programs” (p. 66), it asserts that “all ideologies—whether progressive or traditional, revolutionary or reactionary—entail an aggressive alienation from the existing society,” that “participation in the routine life of the civil political order is alien to the ideological spirit” (p. 68), and that no great ideology has ever considered itself obliged to respect the modern, scientific spirit in its quest for truth (p. 73). Johnson, while apparently agreeing to some extent with this final assertion of Shils’s and offering some important observations about the historical role of the concept, is most concerned to explore the role of ideologies within the theoretical framework developed by Talcott Parsons. Nevertheless, however unscientific it may be thought to be, the term ideology has come to play a very prominent role in the discourses of virtually all of the social sciences, so that it is essential to attempt to clarify its meaning(s).

**ORIGINAL MEANING**

The simple original sense of the term, first deployed by Antoine Destutt de Tracy, was, parallel with the Greek-based names of so many academic disciplines, the study of
Ideology

Ideas. Tracy’s intention, as a materialist philosopher, was systematically to map the material origins or causes of the ideas in people’s heads, and to this end he directed the short-lived Institut de France where such research was undertaken. It briefly enjoyed the favor of Napoleon Bonaparte, who later turned against it. Upon returning from his defeat in Russia in 1812, Napoleon denounced ideology, in an address to the Conseil d’Etat, as a dark metaphysics, dedicated to a subtle search for first causes upon which to base laws. Rather, he urged, laws should be based on a knowledge of the human heart and on the lessons of history. Ideology, he concluded, was responsible for all the misfortunes that had befallen “our beautiful France” (“notre belle France”). In other words, for Napoleon the problem with ideology—quite paradoxically, in light of some contemporary conceptions of it—was that it was based on an excessively scientific philosophy. Since that time, the term ideology has never entirely escaped the pejorative connotations that Napoleon imposed upon it.

Karl Marx and his lifelong colleague Friedrich Engels wrote a lengthy, highly polemical manuscript entitled The German Ideology in which this pejorative sense predominated. Although it was to be the better part of a century before this product of the mid-1840s was published in full, its core notion of ideology was reflected in other works of theirs, such as The Communist Manifesto (1848), and thus became a part of the broad Marxist tradition. According to this notion, ideologies are large thought-systems (e.g., metaphysics, morality, and religion) that in reality have their basis in human beings’ material life-processes, but that mistakenly come to be regarded as independent of the latter and as having a superior life of their own, as supposedly eternal verities. Just such an assumption had been central to the thinking of Hegel, the most influential philosopher during Marx’s early years, who saw history itself as the work and self-realization of a supra-material reality that he called Absolute Spirit, and who tried to show in some detail just how this was so. For Marx and Engels, ideologies typically have the conservative effect of justifying existing relationships of dominance and subordination; thus, according to them, it was not surprising to find contemporary “bourgeois ideologists” defending the capitalist system as the highest and best possible, or in Hegel’s terms as “the end of history.” However, at a time of crisis, which they declared their own era to be, a certain segment of the bourgeois ideologists are able correctly to grasp the movement of history and go over to the side of the subordinate class, the proletariat. In this way, readers might infer, members of this enlightened group (among whom they obviously included themselves) succeed in overcoming and getting beyond ideology.

AmBiguities
But there is sufficient ambiguity in The German Ideology to explain why some of Marx’s intellectual heirs—especially so-called “orthodox Marxists” of the Soviet era—could employ the word ideology in a more positive sense, even referring uncritically to “Marxist ideology” in official textbooks of dialectical materialism. Louis Althusser, a French Marxist theorist who exerted considerable influence during a brief period in the 1960s, regarded ideology as an all-pervasive, inescapable phenomenon, one that is closely connected with Freud’s notion of the “Unconscious”: Ideology, for Althusser, is the mechanism by which, through their imaginations, individuals relate themselves to human existence in different historical epochs. At the same time, Althusser distinguished ideology from science—the latter being, for him, a set of objective concepts detached from interests, the brilliant discovery of which within the domain of history he located in the later work of Marx. (In a very interesting anticipation of what is essentially the same idea—to wit, that there is a strong conceptual contrast to be drawn between science and what others have called ideology—Thorstein Veblen, when discussing the increasingly dominant role of science in the modern world, had also suggested that the continued coexistence, along with science, of more romantic and dramatic as well as pragmatic ways of thinking may be a human necessity.)

By contrast, in his writings of the 1920s and 1930s the Marxist psychologist and psychoanalyst Wilhelm Reich, at once an admirer and a strong critic of Freud, continued to treat ideologies as predominantly negative, repressive phenomena. At the margins of Marxist thinking later in the twentieth century, the French poststructuralist Michel Foucault rejected Althusser’s science/ideology dichotomy and increasingly distanced himself from “ideology critique” in favor of minute, detailed examinations of actual disciplinary and other practices in which there are uneven distributions of power. According to Foucault, relations of dominance and subordination cannot be explained primarily in terms of what neo-Marxist partisans of ideology critique, such as Reich, like to call “false consciousness.”

This same basic ambiguity has also pervaded much of the non-Marxist literature on the subject. Max Weber, clearer than most in this respect, identified two senses of ideology, the first consisting of a reflection of the dominant thought of a given time, the other being the pejorative sense of a manipulative distortion of reality. Johnson, in his previously mentioned Encyclopedia article, makes a small, parenthetical concession to this tradition of ambiguity by explaining that, while from his standpoint the expression ideological distortion is strictly speaking redundant (because all ideology is for him distortive), neverth-
less he would continue to use the full expression, “since this technical meaning of ‘ideology’ is not universally established” (p. 77).

Among treatments of ideology that have been of greatest importance for the social sciences is that of Karl Mannheim, who, in Ideology and Utopia (1929), asserted that, in addition to the “particular” concept of ideology—which equates ideology with a “phenomenon of deception,” or what Mannheim’s Marxist contemporary Georg Lukács called “the reified mind” or more recent thinkers such as Herbert Marcuse often call “false consciousness”—we must also recognize the rise, in modern times, of a “total,” more or less universal concept of it, which sociologists of knowledge can explore across various societies and social groups in an historically “relativizing,” value-neutral way. Mannheim’s advocacy of this kind of theoretically rigorous, scientific, but very broad inquiry seems ultimately to have had the unintended effect of generalizing and “de-fanging” the notion of ideology to such an extent that its contours have become extremely vague and open-ended in much of the more recent literature.

THE “END OF IDEOLOGY”

This tendency was well illustrated in the controversy, which reached its height in the early 1960s, over the alleged “end of ideology.” These words constituted the title of a book by Daniel Bell; other, mainly but not exclusively American, political scientists and sociologists, including Seymour Lipset and Edward Shils, also came to be associated with this idea, which came popularly to be regarded as a literal statement about the then-contemporary historical situation. But, as Shils himself makes quite clear at the end of his Encyclopedia article, neither Bell nor Shils nor most other “end of ideology” scholars intended to make a blanket statement about the demise of ideology in general, as distinguished, at best, from the demise of certain types of ideological thought such as Marxism. This point is particularly well expressed by the fiercely anti-Marxist Raymond Aron at the end of his preface to the new edition of his 1955 book The Opium of the Intellectuals. Aron admits to having previously evoked the end of the age of ideology, and then adds: “But if I detest ideological fanaticism, I like little better the indifference which sometimes succeeds it. … Ten years ago, I thought it necessary to fight ideological fanaticism. Tomorrow it will perhaps be indifference which seems to me to be feared. The fanatic, animated by hate, seems to me terrifying. A self-satisfied mankind fills me with horror” (pp. xv–xvi).

Thus it would appear that social scientists will be unable to dispense with the highly elusive concept of ideology for the foreseeable future, and that, if they ever come to feel that they can, this will probably signify something historically catastrophic.

IGNORANCE, PLURALISTIC

Pluralistic ignorance is a psychological phenomenon in which people think they feel differently from everybody else, even though they are behaving similarly. Consider the following case of pluralistic ignorance: On most college campuses, alcohol use is widespread, and students drink, some to excess, at most social functions. Surveys reveal that most students have misgivings about heavy drinking, particularly when it interferes with schoolwork. Nevertheless, they do not act on these misgivings; instead, they publicly conform to campus norms that prescribe a liberal attitude toward drinking and tolerance for drunkenness. These circumstances give rise to pluralistic ignorance: Students take their peers’ behavior at face value, assuming that everybody else is much more comfortable with heavy drinking than they are.

The study of pluralistic ignorance originated with Floyd Allport, who coined the term in 1928 to describe the situation in which virtually all members of a group privately reject the group’s norms and yet believe that virtually all members of the group privately accept them. In the intervening eighty years, pluralistic ignorance has been linked empirically to a wide variety of collective phenomena, including the failure of bystanders to intervene in
emergency situations, groupthink, the spiral of silence, and the perpetuation of unpopular and deleterious social norms and practices. Once a behavior achieves a high degree of uniformity within a group, pluralistic ignorance fuels its perpetuation.

Pluralistic ignorance often originates in widespread conformity to social norms, driven by a desire both to gain peers’ approval (normatively based conformity) and to do the right thing (informationally based conformity). When this conformity produces consensual behavior that belies private misgivings, pluralistic ignorance is frequently the result. People recognize that their own actions are driven by a desire to be in step with their peers, but assume that everybody else’s actions reflect their private convictions. This dynamic has been shown to produce pluralistic ignorance in a wide variety of attitudinal domains, including students’ attitudes toward alcohol use on campus, nurses’ attitudes toward their jobs, racial attitudes during the civil rights movement, and the opinions of board members about the declining performance of their firm.

Pluralistic ignorance also arises when uniform behavior is driven by other social motives. Consider, for example, the plight of two individuals trying to initiate a romantic relationship. Their interest in each other is mingled with fear of being rejected, and as a consequence, neither is willing to make the first move. Yet, even though both are behaving similarly, they interpret this behavior differently: They see their own inaction as driven by fear of rejection and the other’s inaction as driven by lack of interest. In this case, it is not conformity that produces consensual behavior but rather common fears and anxieties. Pluralistic ignorance results from people’s failure to recognize just how common their fears and anxieties are. This dynamic has been shown to produce pluralistic ignorance in a variety of interpersonal settings, including interactions between potential romantic partners, interracial contact situations, college classrooms, and public emergencies.

ILLUMINATI, THE
Although many groups have referred to themselves as “the Illuminati,” or “enlightened ones,” the term most commonly refers to the Order of Illuminists, an organization founded by Adam Weishaupt (1748–1830), a law professor at the University of Ingolstadt in Bavaria, and four of his friends on May 1, 1776. The Order’s stated mission was “to encourage a humane and sociable outlook; to inhibit all vicious impulses; to support Virtue, wherever she is threatened or oppressed by Vice, to further the advance of deserving persons and to spread useful knowledge among the broad mass of people who were at present deprived of all education” (Johnson 1983, p. 45). While these aims appear moderate, they were in fact a proposal for sweeping social change. The Illuminati and their goals so threatened Bavaria’s political and religious authorities that Karl Theodor, the prince-elector and duke of Bavaria (r. 1724–1799), banned the group in 1787.

The Illuminati emerged as a reaction to the social and political environment of Bavaria in the late eighteenth century. Its institutions were dominated by the Church, and the Jesuits controlled university education. Weishaupt was frustrated by their interference in the university curriculum, particularly their resistance to the dissemination of ideas of the French Enlightenment (Billington 1980). That frustration moved him to create the Illuminati, which he hoped would spread Enlightenment philosophy and put it into practice.

Weishaupt was convinced that a secret society was the most effective way to accomplish these goals, and he utilized his experience with the Jesuits and Freemasons to create his new organization. Although he viewed the Jesuits as his enemies and the Freemasons as conservative and apolitical, he admired their secrecy, discipline, and organization, as well as their capacity to pursue their own interests even (in his view) at the expense of the interests of society as a whole (Roberts 1972). Weishaupt deliberately recruited Freemasons and used the organization’s structure and symbolism as a model for the Illuminati. Members took pseudonyms (Weishaupt became Spartacus) and utilized Zoroastrian symbols to describe themselves and their ceremonies. Initiates read classical political philosophy, and as they moved through the movement’s ranks they were gradually exposed to the Illuminati’s true purpose: to spread the Enlightenment ideas of rationalism and egalitarianism. Only those within the movement’s inner circle, the Areopagus, were told of its related political goals. The Illuminati members were to
infiltrate the social and political institutions of Bavaria and initiate a peaceful revolution. Bavaria would be freed from the tyranny of the Church, and reason and equality would flourish.

Membership in the Illuminati proved tremendously appealing to members of the Bavarian middle and upper classes. From its origins in Ingolstadt, the movement grew rapidly. By 1779, it had members in at least four other Bavarian cities, and by the time it was banned in 1787, its membership numbered between two and four thousand (Roberts 1972).

Although the Order of the Illuminists was short-lived, it had considerable influence. Cloaked in secrecy and symbols, the real substance of the Illuminati was its propagation of Enlightenment ideas. Theodor could declare that anyone caught recruiting new members would be executed and thus ensure the effective end of the organization, but he could not stop the influence of Enlightenment ideas on those who had come into contact with them. The Order’s members were scattered across the upper echelons of Bavarian society, and many were well placed to influence others. Its membership included doctors, lawyers, judges, professors, and government officials. Their exposure to Enlightenment philosophy affected the way they approached politics and probably also influenced those with whom they came into contact. Theodor attempted to purge the Illuminati from positions of power, but military force cannot, in the end, stop the spread of ideas. Illuminism became a source of inspiration for revolutionaries on both the left and right of the political spectrum (Billington 1980).

Weishaupt’s greatest genius may have been his transformation of the secret-society model into an effective political instrument. In devising the Order’s structure and doctrine, he made two important innovations. First, he deliberately created the Order of Illuminists as a political organization. He understood that secrecy could be not only an end in itself but also a political strategy. Second, he used existing secret organizations—namely, the Freemasons—for his own ends. In doing so, he created a network of secret societies that could be used for his own political purposes. While these achievements furthered his immediate goals, they also insured the Illuminati a place of particular importance in the history of conspiracy theories.

Conspiracy theories—expressing the belief that some covert power with malicious intent is directing world affairs—became a popular mode of political explanation in the early twentieth century, and they remained popular into the twenty-first century. Typically, conspiracy theories emerge during times of social change; they provide believers with a sense of certainty in uncertain times. The Illuminati play a pivotal role in many of the most influential modern conspiracy theories; the organization is, for example, believed in league with forces as diverse as aliens, Jewish financial power, and the individuals behind the events of September 11, 2001. Most scholars argue that the Order of Illuminists does not control history in this way. While political conspiracies have certainly existed—secrecy is often an element of political strategy—human beings exist in a contingent world and are limited in their ability to control history.

The Order of Illuminists therefore remains relevant today. It is most effectively understood as an eighteenth-century model of the power of secrecy and the use of allies in executing political strategy.

IMMIGRANTS, ASIAN

Asian migrations to the United States form one aspect of a dynamic, global social process that has seen peoples from Asian nations create new communities in such diverse destinations as the United States, Cuba, Canada, Mexico, Peru, the United Kingdom, East Africa, South Africa, and nation-states in Europe. This demographic movement happened over a long period of time and it continues to this day. The U.S. chapter of this worldwide story is both emblematic of these processes and singular in its own right.

When one speaks of Asian migrations to the United States one must underscore the diversity of these movements. Before World War II (1939–1945), Asian migration flows came from five major streams originating from particular regions in China, Japan, Korea, the Philippines, and India. After World War II, and especially after 1965...
and 1975, Asian flows diversified to include South Asia and Southeast Asia. From the former came entrants from Pakistan, India, the Maldives, Nepal, Bhutan, Bangladesh, and Sri Lanka. From the latter came Vietnamese, Hmong, Laotian, Cambodian, and Thai contributors to modern Asian America.

The long roots of Asian migration can be traced as far back as 1763, when shipworkers from the Philippines, "the Manila men," established themselves as a community in what is today Louisiana. Other pioneer Asian arrivals came earlier than the better-known migrations to California in the 1840s, and they showed up on the Atlantic Coast, not the Pacific. In 1785 a ship with a crew of "Chinese, Malays, Japanese, and Moors" arrived in Baltimore, and South Asians worked in Massachusetts and Pennsylvania as indentured servants in the 1790s. By 1856 an estimated 150 Chinese lived in lower Manhattan in New York, working such jobs as sailors, ship workers, cooks, and stewards. These forgotten early Asian settlers on the Atlantic Coast preceded the Asians and Pacific Islanders who were lured to California by the gold rush of the late 1840s.

Chinese settlements produced political and social reactions in the United States, particularly in California after 1850. This agitation continued and grew in force until it culminated in the 1880s with Congress passing the first Chinese laborer suspension act, thus creating the Chinese exclusion system. From 1882 to 1904 the U.S. Congress passed at least seven major amendments that continued and amplified the Chinese exclusion statutory regime. Ostensibly promulgated to suspend Chinese laborer migration for a period of time, the laws had the overall social and legal effect of controlling the movements of Chinese-derived persons, both across the Pacific and across the United States.

Although exclusion was technically limited to the Chinese, the logic of the exclusion laws could be applied to other Asian immigrants and their communities. That logic found its most powerful expression in the legal idea of ineligibility for citizenship. Based on a judicial decision in 1879 that declared Chinese to be ineligible for U.S. naturalization, various federal judges applied the same racially based rule to other Asian groups and individuals. As a result, state governments barred persons ineligible to be citizens from owning property and pursuing a range of occupations. This logic was adopted by the Supreme Court in two decisions in 1922 and 1923 that successively denied U.S. naturalization to those of Japanese descent and those of "Hindu" or South Asian origins.

As exclusion grew, so did the territorial reach of the United States. When the United States made its foray as a world power after defeating Spain in the Spanish American War in 1898, it asserted control over Spain's former Pacific possession, the Philippine Islands, thus precipitating another stream of Asian migration. Filipinos moved to the United States to work in California agriculture in the 1920s and 1930s, or to take up university scholarships provided by the government. At the same time, exclusionary rules were being applied to Chinese living in the Philippines. In addition to the Philippines being included under Chinese exclusion, would-be migrants from other areas of the Pacific, East Asia, and the Near East fell under exclusionary bans inspired by the Chinese exclusion precedent. On February 5, 1917 the U.S. Congress banned the entry of aliens from a large segment of the world marked off as the "Asiatic Barred Zone," an area that included Indochina, India, Burma, Thailand, the Malay States, the East Indian Islands, Asiatic Russia, the Polynesian Islands, and parts of Arabia and Afghanistan. With the exception of teachers, merchants, and students, no one from the zone was eligible for U.S. entry.

The U.S. involvement in World War II was a watershed era for all Asian-derived communities in the United States. Chinese exclusion came to a formal end in December 1943 when the U.S. Congress repealed it in an attempt to bolster China as a wartime ally. Korean Americans living in the United States, along with other Asian-derived Americans, joined the U.S. armed forces. Filipinos benefited from an improved public image due to their homeland's resistance to the Imperial Japanese Army. During the war, South Asians were emboldened to seek U.S. citizenship rights, and both Filipinos and South Asians received U.S. naturalization rights in 1946. Although these communities gained from the U.S. involvement in the war, Japanese Americans were forcibly evacuated and interned. From 1942 until the war's end, 110,000 Japanese who resided in Oregon, Washington, and California, most of whom were native-born U.S. citizens, were ousted from their homes and livelihoods on the U.S. west coast and sent to relocation camps in the country's interior. This involuntary removal, unmatched in history in terms of its scale and scope, was in effect a mass incarceration.

After World War II, cold war immigration patterns reshaped both the United States and that of Asian America. Those patterns benefited from the halting yet persistent reform trends set in motion by the repeal of Chinese exclusion in the mid-1940s. Twelve years after the repeal, Congress enacted the 1952 McCarran-Walter Act, which brought forward the reform trends of 1943 to 1946 but also set new limits to Asian migration. The 1952 law allowed U.S. citizenship and naturalization for all Asian-derived individuals, thus removing a key disability, but it also replaced the Asiatic Barred Zone with the "Asia Pacific Triangle," a provision that simultaneously provided new entry quotas for twenty Asian nations and stipulated
an overall low ceiling on how many Asians were eligible to enter. It was not until the civil rights era that the most important immigration law to shape modern Asian Pacific America came to be. In 1965 Congress undid the restrictive immigration laws that had hampered non-Chinese Asian migration since 1917 by passing the Immigration Act of 1965, allowing for greater numbers of Asian immigrants. The act was passed at the juncture of the civil rights movement and the beginning of the U.S. ground war in Vietnam. Ten years later, the U.S. military and political presence in Vietnam ended. In spring 1975 U.S.-backed regimes in Southeast Asia fell, thus inaugurating flows of Vietnamese, Cambodian, and Laotian refugees to the United States. The diversity of Southeast Asian migrations from 1975 to 1980 and thereafter is as striking as any of the pre–World War II migration flows from Asia.

Although the mid-1960s saw civil rights and immigration reforms for Asian-derived communities, the same era also burdened all Asian Pacific American communities with a new stereotype—Asians as the “model minority.” On its surface this was an improvement over exclusion-era denigrations, but the “model minority” label actually obscures the lived realities of many Asian American individuals and communities by claiming that Asians have overcome all the barriers faced by exclusion-era Asians. Although the harshest aspects of exclusion have ended, and many Asian American communities and individuals have moved beyond the stereotypic urban niche occupations of laundry work, the model minority claim is really myopic. The label obscures and sidesteps the realities of Asian Pacific American experience: continued poverty; the historical and social conditions that privilege, in some Asian communities, the immigration of already trained professionals who enter more readily into middle-class positions; and the hidden costs of extra work and long hours that enable the middle-class attainments of home ownership and better education for children. Also kept out of view is the glass ceiling that limits and frustrates professional advancement. In the end, the model minority notion is never about actually lived Asian American lives; it is always about the conceit of holding onto beliefs that celebrate ideals about social mobility in the United States.

Asian migrations did not stop with the end of the cold war. The flow of people from every imaginable Asian starting point continues, and the vibrancy of Asian American communities throughout the United States is impressive. These contemporary Asian migrations build upon the legacies of earlier movements. Although separated by different historical experiences, these communities all share the legacy of persistence and survival that characterize the long sweep of Asian American history.

IMMIGRANTS, BLACK

The black population in the United States has always been diverse in terms of national origins. A sizeable influx of black immigrants from the Caribbean, Latin America, and sub-Saharan Africa added to that diversity in the second half of the twentieth century. Significant differences in the factors that stimulated migration, characteristics of the migrants, and the contexts they encountered make it possible to speak of two generations of black immigrants: the pre–World War II wave that arrived primarily between 1900 and 1930, and the post-1965 wave that swelled after the Hart-Celler Act (Immigration Reform Act of 1965) and other immigration-policy changes in the United States and Europe.

THE FIRST GENERATION OF BLACK IMMIGRANTS

Although the number of black immigrants historically has been quite small, their presence in the United States dates back to the turn of the last century. According to Ira A. Reid, at a time when U.S. immigration was at its peak (between 1880 and 1930), foreign-born blacks comprised...
only 1 percent of the total black population (Reid 1939). By the end of this era of mass migration, nearly 28 million immigrants had entered the United States; of that number approximately 100,000 persons were socially defined as “Negro immigrants.”

The first generation of black immigrants came primarily from the Caribbean region, Canada, and the Cape Verde Islands (a Portuguese colony off the west coast of Africa). The forces that prompted and sustained the migrant flows were fundamentally political and economic. In the British or anglophone Caribbean, oppressive colonial policies, economic distress, and natural disasters, together with opportunities abroad, occasioned mass migration to the Panama Canal zone, to sugar plantations in the Dominican Republic and Cuba, and most notably to the industrializing United States. Similarly, Cape Verdiens fleeing drought, famine, and a lack of rewarding employment migrated to southeastern New England in search of lucrative, short-term employment.

The immigrants were mostly males in their wage-earning years; over 36 percent were between the ages of sixteen and thirty-seven years old; and the majority was not married. Many had been skilled artisans, bankers, merchants, colonial civil servants, and professional persons in their countries of origin. Because immigrant laws selected for literacy, more than 98 percent were literate when they arrived and, with the exception of less than 2 percent, they spoke English. Although the migrants represented a select segment of their home societies, in general they were future male industrial workers and female domestic servants.

These foreign-born blacks tended to settle in urban areas—especially New York, Miami, and Boston, which served as primary ports of entry. Cambridge and New Bedford, Massachusetts, Tampa, and Detroit also had sizeable black immigrant populations. Cigar manufacturing in Florida pulled migrants to Tampa; and black immigrants found work fishing, whaling, and, later, in the cranberry industry in New Bedford. Where certain groups settled had as much to do with the economic opportunities there as how they were located or perceived in the social hierarchies of each city or region. Notably, with the exception of Florida, few black immigrants settled in the U.S. South.

For the black immigrants who arrived at the turn of the last century, their hyperracialization as blacks had the most profound impact on their experiences. For the most part, distinctions of color, language, education, economic status, religious practice, and nationality mattered little in a society with a racial hierarchy held together by an ideology of biological inferiority. Whether or not they lived their lives as Haitians, Jamaicans, Nigerians, West Indians, or Africans, what the historian F. James Davis calls “the one-drop rule” of racial classification consigned black people of all classes to the bottom of the social ladder and was the basis for their exclusion from economic and educational opportunities (Davis 1991). Not only did they suffer from the same rigid segregation and blanket discrimination as native-born black Americans, in addition, they were rarely considered as part of the British or Portuguese immigrant communities. In a seminal essay, Roy S. Bryce-Laporte argued that for black immigrants, incorporation into the larger African American community generated an additional layer of social marginality; they were invisible both as blacks and as immigrants (Bryce-Laporte 1972).

BLACK IMMIGRANTS TODAY

The visibility of black immigrants has dramatically increased since the 1970s. In the ten years following the Hart-Celler Act, the number of black immigrants exceeded the total from the previous seventy years. Black immigration continued to grow in volume after that. Demographer John Logan and his colleagues show that black immigrant groups are growing faster than well-established ethnic minorities such as Cubans and Koreans (Logan 2003).

Unlike the first generation of black immigrants, the post-1965 wave is much more diverse in terms of both country of origin and type. In addition to the 1,393,000 newcomers from the Caribbean (primarily Jamaica, Haiti, and Trinidad and Tobago), in 2000 there were nearly 600,000 African immigrants living in the United States. (Notably, there is no consensus in the scholarship about how to count black immigrants. The U.S. Census and the Immigration and Naturalization Service report the foreign-born by place of birth. Because not all African immigrants are black—consider the case of Egyptians or South Africans—and a considerable number of Latin American immigrants—from Cuba or Puerto Rico, for instance—identify as black, all enumerations of the population of black immigrants are estimates. The estimates reported here are based on sample data from the U.S. Census Bureau for the foreign-born population born in all nations of the Caribbean except Cuba and Dominican Republic, eastern Africa, and western Africa.)

The end of World War II produced significant political changes in many African countries, and in some cases political instability, economic mismanagement, and civil unrest in the wake of independence triggered migration. The main sources of African immigration are Nigeria, Ghana, Cape Verde, and more recently, the Horn of Africa—including Ethiopia, Eritrea, Somalia, and the Sudan.

immigrants. Since the publication of Reid’s pioneering work in 1939, scholars have been most concerned with what the experiences of black immigrants tell us about race in the United States. One noteworthy debate concerns the relative importance of race and ethnicity in determining socioeconomic success.

As Table 1 summarizes, contemporary immigrant blacks seem to fare better than native-born blacks on a number of socioeconomic indicators (Logan 2003): They have higher education and income levels, and a substantially lower percentage are unemployed or below the poverty line. Analyses of U.S. Census data also reveal that in the metropolitan areas where they live in largest numbers, black immigrants tend to reside in neighborhoods with higher median incomes, higher education levels, and higher proportions of homeowners than do African Americans. Some researchers have used such indicators to argue that race and discrimination are no longer significant determinants of life chances.

Moreover, recent research shows that the representation of blacks with immigrant-origins at selective colleges and universities is roughly double their share in the population (Massey et al. 2007). Whereas only 13 percent of all black Americans between the ages of 18–19 were either foreign-born or the children of migrants, sociologist Douglas Massey and his colleagues found that among the black college freshman entering selective institutions in 1999, 27 percent were first- or second-generation immigrants. Their research, along with previous work which suggests favoritism toward black immigrants by white employers, calls into question, not only the efficacy of affirmative action programs, but also whether black immigrants are the appropriate beneficiaries of such policies in

education and employment designed to ameliorate the past exclusion of native-born, African Americans.

However, beneath the apparent differences between the majority of blacks with historical origins in slavery and in the rural South and black immigrants from the Caribbean and Africa is a shared experience of race-based discrimination. The relative success of foreign-born blacks is partly due to the size of the black immigrant population: Even with the current rate of growth, they comprise less than 1 percent of the total population of the United States and only 6 percent of the non-Hispanic black population. For this reason, it is important to note how black immigrants are doing relative to whites and other immigrants. Compared to Asian immigrants, for instance, foreign-born blacks have appreciably lower median household incomes ($42,000 compared to $62,500), higher rates of unemployment (6.5% and 5.8%, respectively), and a larger proportion living in poverty (15.9% compared to 12.7%). Moreover, black immigrants, like African Americans, are highly segregated from whites; and regardless of nativity, non-Hispanic blacks live in worse neighborhoods than do non-Hispanic whites. With respect to academic achievement on college campuses, black students of all backgrounds do not perform as well as whites with similar characteristics. So far, the empirical evidence suggests that institutional and societal processes have a differential effect on black immigrants, compared to native-born blacks, not that there are discernible cultural differences at work. As Mary Waters concluded in Black Identities: West Indian Immigrant Dreams and American Realities (1998), race still shapes everyday life for black immigrants and their offspring.

THE FUTURE FOR BLACK IMMIGRANTS

Black immigrant communities will continue to be part of the U.S. ethnic mosaic. Contemporary black immigrants encounter a U.S. context that is more diverse, with considerably more recognition of the diverse national origins of blacks than ever before. According to Philip Kasinitz (1992), the racial structure of the United States prevented cultural self-determination and self-representation among black immigrants for most of the twentieth century. Within the black community, attempts by black immigrants to distinguish themselves from the native-born were considered divisive and ethnocentric. Today, the larger numbers of black immigrants, the uninterrupted flow of newcomers, and the new U.S. context have created a space for the consolidation of distinct black ethnic communities, subjectivities, and social identities.

IMMIGRANTS, EUROPEAN

Humans migrated to European regions from Africa approximately 40,000 years ago and have been moving ever since. Europeans seem to be highly related to the same northeastern Africans who settled much of Asia and the Middle East, or Eurasia. Thus, it is hypothesized that there were numerous movements of tribes and peoples both eastward and westward across Eurasia in the years before the early middle ages. Knowledge of their movements is more accurate around 2000 BCE, once Europeans started keeping track of their history through books and oral traditions. As archaeologists and geneticists complete more studies, more precise details of migration patterns from more than 2,000 years ago may come to light.

EUROPEAN MIGRATION, 1000–1800

Some historians believe that migration movements were common in the early middle ages, but solitary migrations were rare and people tended to move in midsize groups.
Later this reversed, and migrations of solitary individuals or small groups became more common. Still, voluntary immigration movements were rarer in the few centuries after the fall of the Roman Empire than they are today. Travel around Europe was difficult, slow, and dangerous, and mostly restricted to merchants, ambassadors and envoys, and pilgrims. Before 1000 CE, traveling from Italy to Constantinople, for instance, could take at least seven months, although travel times gradually became shorter over the centuries. A few people migrated to parts outside of Europe, but this was rare and involved mostly people engaged in embassy work or associated with religious institutions. A notable exception, however, was the settlement Vikings established in Newfoundland around the year 1000, although it was abandoned after only a few years.

What was more common was involuntary migration in the form of the transportation of slaves. Slaves, with no choice in the matter, could walk long distances and even carry things for their owners. Most individuals became slaves through a slave raid on their community or as a result of military action. In the early middle ages, many slaves came from towns along the Mediterranean coast and in the eastern “Slavic” parts of central Europe. Arab raiders liked to find their potential slaves in southern European coastal villages, and Frankish tribes found many of their slaves first in England and later in the East. Slaves could be sold at many organized markets, most of which were located in the European and Arab parts of the Mediterranean world.

Several main immigrations to places outside of Europe occurred between the tenth and fifteenth centuries. Victorious armies or raiders continued to capture and enslave people, who ended up typically in the Mediterranean area where slaves were extensively used, which included northern Africa and the Ottoman and Arab/Muslim world. Secondly, in the thirteenth and fourteenth centuries, under Mongol protection, some Italian missionaries made it to Asia on the heels of Venetian traders such as Marco Polo. In addition, crusaders from Europe invaded the Holy Land in 1099; some integrated into society or settled in other places such as Constantinople, but many of their descendants moved back to Europe once Turkish and Kurdish rulers claimed Jerusalem in 1187. Thereafter, pilgrims still visited but did not usually settle in the Holy Land.

As in the early middle ages, merchants, traders, sailors, and government and religious officials all were more likely to venture beyond the borders of Europe. Significant group migrations also took place in this time period. In the thirteenth and fourteenth centuries Jews were expelled from many parts of Europe, and some ventured to eastern parts of the continent. Others, including many of the Sephardic Jews of Iberia, left in 1492 for parts of the Ottoman Empire, including Palestine, Syria, Tunis, Egypt, Morocco, and Constantinople. During the same period, the Spanish and Portuguese also placed restrictions on the commercial and religious practices of Muslims, who were eventually completely expelled from the Iberian Peninsula by the mid-seventeenth century. Many of them left for communities in the Ottoman Empire.

By the 1400s Europeans were using better ships and navigational technology and were sailing farther away from their continent. Portuguese explorers made inroads in sailing around Africa and eventually all the way to parts of Asia, while the Italian explorer Christopher Columbus, funded with Spanish money, made it to Central America. Thereafter, it was a race for European nations to settle and claim different parts of North, Central, and South America, Africa, parts of Asia, and Australia and New Zealand. The search for colonial possessions lasted until the twentieth century.

The Portuguese were prodigious in establishing trading stations on the coastlines of Africa and Asia along with the settlements in Brazil, and all of this required a lot of manpower. From the sixteenth until the eighteenth centuries large numbers of Portuguese left their homeland to serve in various roles, as soldiers, settlers, and missionaries. Even though Spain was colonizing large parts of the Americas, during this period more people left Portugal than Spain.

Nations that created settlements or colonies provided destinations for their countrymen who wanted to leave Europe; trading networks that emerged between Europe and new settlements provided the necessary transportation for migrants. Before 1800, for example, Britain at different points in time had claim to Australia, New Zealand, the American colonies, Canada, some Caribbean islands, and British Guyana, among others; later, for periods of time it controlled various African areas including Egypt, Rhodesia, Nigeria, and South Africa. France at one point claimed parts of present-day Canada, various Caribbean islands, French Guiana, Cambodia, Vietnam, and a host of African countries. In addition, Belgium, Denmark, Germany, Italy, the Netherlands, Portugal, and Spain also exercised their imperial ambitions and operated various colonies at some point.

Most of these colonies no longer exist, but their existence influenced the patterns of European settlement from the sixteenth to the twentieth centuries. As British colonies, Australia and New Zealand, for instance, became a major settlement for British and Irish emigrants. In Africa, many British emigrants settled where the British had set up colonies, including South Africa and Rhodesia. French emigrants settled in French colonies such as Quebec; likewise, many Portuguese emigrants settled in...
Brazil, and numerous Spaniards in Spanish settlements throughout the Americas. The various Dutch colonies attracted thousands of Dutch emigrants, particularly to the East Indies. Those with ambition but no financial assets could sign on as soldiers or for work with companies such as the Dutch East India Company. Colonies needed laborers and thus provided ways for impoverished individuals to emigrate from Europe. Until the 1830s a very common way to migrate to the British colonies in North America was by way of indentured servant contracts, which provided prepaid passage in exchange for future years of labor services.

1800 TO THE PRESENT

Emigration from Europe increased remarkably in the nineteenth century, partly as a result of increases in population growth along with changes in emigration policies. Before the nineteenth century Europe’s population doubled approximately every 1,000 years, but by the nineteenth century population growth had increased tremendously, such that Europe’s population doubled in less than 100 years during the nineteenth century. In addition, the Vienna Congress in 1815 extended the right to emigrate to many more Europeans. The period after 1815 thus saw a tremendous increase in the numbers of people who left Europe permanently and voluntarily. Between 1815 and 1930 more than 52 million Europeans left Europe for overseas destinations. About two-thirds went to the United States, and most of the rest to South America: Approximately 12 percent went to Argentina, 8 percent to Brazil, and 7 percent to Australia. Over this period, 11 and 10 million of these European emigrants left from Britain and Italy, respectively. Other countries that lost more than 2 million individuals include (in order of largest to smallest) Austria-Hungary, Germany, Spain, Russia, and Portugal.

Emigration rates—the percent of the population at home that leaves—differed tremendously across different countries. If a country had a small population overall, it could lose a small number of individuals to migration movements but still have a high emigration rate. This was the case for Ireland: Until 1900, Irish emigration rates were the highest by far of all European nations. During several decades annual Irish emigration rates reached 14 per 1,000 of the home population; the next highest annual rates occurred in the 1880s with Norway losing 10 per 1,000 and Scotland 7 per 1,000. In the years after 1900 emigration rates were still high for Scotland, but also very high for Italy and Spain. Although a high emigration rate often reflected poor economic conditions within certain regions of a country, it also could signify a late or slow demographic transition, or an arduous adjustment from an agricultural economy to an industrial one that left many without viable livings as farmers or craftsmen. Some areas suffered terrible exogenous events such as the potato famine of the 1840s, which occurred throughout much of Europe but hit Ireland especially hard.

In the nineteenth century it was not always the case that European emigrants were the very poorest. The fact that moving overseas was an expensive proposition meant that many potential emigrants without a remittance of some sort did not leave Europe because they could not afford to do so. In many regions both the richest and the poorest stayed home, the former because they had no interest in leaving and the latter because they could not afford to do so. That many emigrants ended up depending on family or friends who had moved before them for financial assistance or advice to achieve their goals meant that many emigrants left from the same European villages or regions; in other regions such chain migration connections did not evolve, and these areas experienced much less emigration.

Improvement of one’s standard of living was of primary concern for many European emigrants over the centuries, but many moved for religious or political reasons. Various Christian groups settled in North America, including Pietists, Calvinists, Mennonites, Amish, and others. Jews from various parts of Europe, but especially those who suffered the nineteenth-century pogroms of Russia, sought new homes overseas. Political uprisings in Europe such as the Revolutions of 1848 encouraged at least a few individuals to leave Europe permanently. Colonial powers also found their new territorial possessions convenient as dumping grounds for the convicts they wanted to get rid of in the home country.

Traveling by sailing ship was the norm until the latter half of the 1850s, when steamships were introduced, dramatically changing the nature of migration. Whereas a voyage from England to New York could take six to eight weeks by sailing ship, steamships cut the time down to less than two weeks. This meant less time out of work while en route and a smaller probability of contracting a disease on board. The less arduous traveling conditions and the gradual drop in passage fares (in real terms) over time made both seasonal and return migration more possible. Emigrating from Europe to overseas destinations in the era of the sailing ship had mostly involved permanent moves, but this new technology and lower passage prices changed that.

The years before the 1920s were the golden age for European immigrants as most destination countries granted them access without much reservation. During the 1920s many of the popular destination countries passed legislative measures establishing restrictions on the number of annual immigrants. Today, most countries practice immigration regulations based on national-origin quotas and limits on the total numbers of annual immigrants.

IMMIGRANTS, LATIN AMERICAN

Immigration from Latin America closely tracks several factors: U.S. foreign policy, both economic and political; U.S. domestic economic policy; and political and economic crisis in the home countries. In some cases, the arrival of Latin Americans to the U.S. mainland is less “immigration” of foreign nationals than “migration” of U.S. citizens from, for example, Puerto Rico.

U.S. economic pressures play a major role in Latin American migration. Business interests desire the low-cost labor that immigrants represent. Labor leaders, immigration-opponent organizations, and individuals argue that immigrants undercut the wages of U.S. workers and cost taxpayers in the form of public services. Immigration advocates defend their presence and advocate for the humane treatment of immigrants; they argue that without immigrants, U.S. industry would come to a standstill. Virtually voiceless are the immigrants themselves, who are unable to exert political pressure.

From the standpoint of the sending Latin American countries, emigration often represents an escape mechanism, with employment opportunities not available at home. In addition, remittances sent back to home countries through wire transfers allow individual families and communities necessities they would otherwise forego.

In terms of foreign policy, U.S. immigration policy is generally determined by whether the home country is seen as a threat to the U.S. way of life.

THEORETICAL FRAMEWORKS

Social scientists have applied various theoretical frameworks to immigration. The melting pot, or assimilation perspective, in which newcomers to the country blended into one “America,” seems to have fallen short of the mark when it came to Latinos in the United States, who maintain their cultural identity even after several generations.

Another theoretical framework that gained favor in the 1970s was the internal colonization model. Subscribers to the internal colonization model noted that the “melting pot” did not apply to people of color. Mario Barrera, for example, noted that internal colonization is especially discernable in particular in areas where the colonized are in the majority, but not in control (1979).

Latino immigrants, like immigrants from other continents, often straddle their home countries and their new countries. In this pattern of settlement, sometimes referred to as “transnationalism,” immigrants maintain close ties to their homelands and, in fact, send remittances to sustain family ties. In “diasporic citizenship,” immigrants maintain such close ties to their home countries that they are able to effect occurrences there while also exercising some power in their new countries.

MEXICAN MIGRANTS

Mexican migration offers the most salient and large-scale story of U.S. immigration policy, due to the countries’ shared history and their common 2,000-mile border. Mexicans made up 30.7 percent of the foreign-born persons living in the United States in 2005, the largest nationality by far. To understand the relationship of Mexican immigrants to the United States, one must consider that in 1848 Mexico lost the U.S.-Mexico War and was forced to sell to the United States for $15 million what is now California, New Mexico, Nevada, and part of Colorado and Arizona.

Mexican immigrants have felt the brunt of U.S. immigration policy changes. For instance, during the Great Depression an estimated 200,000 Mexicans returned voluntarily to Mexico, but between 1931 and 1932, an estimated half-million people were deported to Mexico. Later, when the United States faced a labor shortage during World War II, the U.S. and Mexican governments signed an agreement for the importing of braceros, agriculture and railroad workers. The Bracero program was renewed annually, until it was terminated in 1964; in 1965, Operation Wetback deported thousands of Mexicans.
PUERTO RICANS
Spain conquered Puerto Rico in 1493, when Columbus landed there on his second voyage to the New World. Although the Spanish-American War of 1898 was fought over Cuba, the treaty that was signed in Paris in December 1898 also gave the United States control over some of Spain’s other possessions, including Puerto Rico, Guam, and the Philippines, which were sold to the United States for $20 million.

The first migration of Puerto Ricans to the U.S. mainland lasted from 1900 until 1945, and the main destination was New York City. By the end of World War II Puerto Ricans numbered 135,000 in New York City. A second large migration lasted from 1946 to 1964. In the mid-1960s Operation Bootstrap lured industry to Puerto Rico with the promise of low wages, tax-free operations, and duty-free exports to the mainland. Although the program was saluted as a success, one negative effect was that rural Puerto Ricans abandoned their homes for the promise of jobs in the cities. When there were not enough jobs, Puerto Ricans left home and arrived in the mainland. By 1980 more than 80 percent of Puerto Ricans lived outside of the island.

Puerto Rico has a nonvoting commissioner representing the island in the U.S. Congress. Puerto Ricans may not vote in national elections, but they are eligible to participate in party primaries. A continuing and persistent debate for Puerto Ricans is whether to continue the status quo as a possession of the United States, or to advocate for statehood, or to demand independence. The writer Juan Gonzalez notes that the Puerto Rican migrant experience is “the contradiction of being at once citizens and foreigners” (Gonzales 2000, p. 82).

CUBAN IMMIGRANTS
The Cuban immigrant population dates back to the late 1880s, and has included waves of people who vary in educational and class backgrounds. The first groups settled in New York City, Philadelphia, Tampa, and Key West. Cuban immigrant cigar makers created Ybor City, outside of Tampa, as early as 1886.

In 1898 an explosion aboard the U.S.S. Maine in the port of Havana prompted the United States to step in on the conflict that had raged between Spain and Cuba for thirty years. Spanish forces were quickly squelched in what became known as the “Spanish-American War,” and the Treaty of Paris ending the war was signed by the United States and Spain—without the participation of Cubans. The United States governed Cuba until May 20, 1902.

The story of contemporary Cuban immigration begins after 1959, when Fidel Castro (b. 1926) and revolutionaries ousted Fulgencio Batista (1901–1973) from power. Cuba’s elite arrived in the United States immediately, expecting that the United States would oust Castro quickly. This first group of exiles supported military intervention. Thousands underwent U.S.-sponsored training in Central America, and on April 17, 1961, armed exiles invaded Cuba at the Bay of Pigs, expecting U.S. air cover, which never materialized. Sixty-eight people were killed and the Castro government took 1,209 exiles prisoner. They were released in December 1962 in exchange for $53 million in medical supplies, food, and money.

The Cuban exodus included more than 14,000 unaccompanied minors who arrived between December 1960 and October 1962. After Castro announced his allegiance to communism, middle-class Cubans, fearful of the future, put their children on U.S.-bound flights to be met by relatives or, sometimes, by strangers participating in what later became known as “Operation Peter Pan.”

A third wave of Cuban immigrants came after hundreds of Cubans sought asylum at the Peruvian embassy in April 1980. Castro announced that whoever wanted to leave could do so—provided someone arrived to take them from the port of Mariel. Those émigrés came to be called Marielitos. A fourth wave, in the mid-1990s, was prompted by the continuing deterioration of Cuba’s economy. These people were known as balseros, after the small boats and homemade rafts they used to navigate the 90-mile journey to the Florida Keys. Between August 5 and September 10, 1994, the U.S. Coast Guard picked up 30,305 balseros.

The United States, in an attempt to weaken the Cuban regime, has made considerable efforts to help Cuban immigrants, calling them “refugees” fleeing communism and making available various federal programs to smooth their adjustment. Federal funds were allocated for resettlement, monthly relief checks, health services, job training, adult-educational opportunities, and surplus food. The federal government also provided grants to Florida colleges and universities to train Cuban teachers. Other aid included a loan program for Cuban college students.

Cubans have transformed south Florida. María Cristina García (1996), referring to the strong anti-Castro sentiment, notes that residents of Miami joke that Florida is the only state in the union with its own foreign policy. At times, anti-Castro fervor has led to violence against those who want a normalizing of relations with Cuba. As the numbers of Cubans in Florida has grown, a public backlash has occurred. In Dade County in 1980 voters repealed the 1973 Bilingual-Bicultural Ordinance, so county funds can no longer be used for programs supporting any language other than English, or for promoting any culture other than that of the United States.
CENTRAL AMERICAN IMMIGRANTS
Most of the immigrants from Central America have come from three nations: Nicaragua, El Salvador, and Guatemala. The difference in the treatment of refugees from the three countries was particularly stark in the late 1980s, when Nicaraguans were fleeing a Marxist government, and the Salvadorans and Guatemalans were fleeing conservative governments and civil war: The U.S. government granted asylum to only 2.6 percent of Salvadorans and only 1.8 percent of Guatemalans, but 25 percent of the Nicaraguan requests for political asylum were approved.

IMMIGRANTS, NEW YORK CITY
For most countries, immigration constitutes an engine of transformation. For the United States, New York City serves as a symbol of the many peoples from all over the globe who have arrived in the country. It also serves as a microcosm of the complex cultural, political, and socio-economic issues that immigration gives rise to.

By the time the first Europeans sailed into what is today New York City in the early sixteenth century, the migration of indigenous people into the region had been occurring for thousands of years. The Lenape—who spoke the Algonquin language—populated the area at the time. The influx of European immigrants was slow at first. It was not until the third decade of the seventeenth century that the first major wave of European immigrants settled in the New York City area. The largest immigrant groups were of northern and western European background. Dutch immigrants were the first to locate in what is now Manhattan, founding a settlement they called New Amsterdam. African populations also made an early appearance in the region. On September 15, 1655, the ship Witte Paert brought 300 African slaves to New Amsterdam. By 1664, the black population was estimated at between 20 and 25 percent of the total.

In the summer of 1664, New Amsterdam fell to the British. In 1674, the colony was granted to James, the Duke of York, giving New York its name. The Dutch remained the largest immigrant group throughout the seventeenth and eighteenth centuries, followed by French Huguenots. Over 60,000 people resided in the city in 1800.

Immigration into New York greatly expanded in the period between 1815 and 1880, which became known as the Old Immigration era. The immigrant flow from northern and western Europe continued, but from different countries. Hundreds of thousands of Irish and German immigrants moved into the city, followed by English and Scots. By 1860, New York City had 813,669 residents, out of which 383,717 were foreign-born, including 203,740 Irish and 118,292 Germans.

IRISH AND GERMAN IMMIGRANTS
The Irish migration to the United States in the nineteenth century was motivated by a wide array of forces. The American economy had been expanding rapidly and was an attractive source of jobs. New York City itself was booming as a result of the opening of the Erie Canal, which allowed transportation of goods along the Hudson River all the way to the Great Lakes. At the same time, what is now Ireland had become the most densely populated part of Europe, with hundreds of thousands of young workers desperately looking for employment, some in the United States. Immigration peaked in the 1850s, when close to a million Irish moved to America. This migration surge was a result of sharply deteriorating economic conditions in Ireland. In 1845, a fungal disease viciously attacked Irish potato fields, leaving crops almost entirely destroyed. Famine and disease followed, with more than a million people dying and many others fleeing...
to the United States and other countries in the ensuing decade.

Many of the Irish immigrants were poor and unskilled. They lived in tenements, which were large, cramped, multifamily housing units with scant plumbing, heating, or lighting. They were often discriminated against and vilified for taking employment opportunities from U.S.-born Americans. Nativist groups, whose ideology was that the immigrants were hurting the American economy, society, and culture, campaigned against Irish immigrants, often spreading bigoted views of the Irish. Like other immigrant groups, the Irish were initially marginalized from the city’s social and political mainstream. Historians such as Noel Ignatiev and David R. Roedinger find that these immigrants were considered racial minorities at the time, not part of the white population of the city. This poverty and social exclusion exploded in the draft riots of 1863. In July, as the names of thousands of Civil War draftees were announced, many poor Irish who could not pay the $300 draft waiver ran into the streets of the city in protest, burning buildings, looting stores, and assaulting and killing thousands of people. Black residents of the city came under savage attacks that were fueled not just by prejudice but also by the rioters seeking a scapegoat, blaming blacks for their many miseries, including the Civil War draft, low wages, and lack of employment opportunities.

Despite the initial barriers, Irish immigrants gradually progressed in the economy and in society. Because of their growing numbers, they were able to exert considerable political influence in New York City’s government institutions, especially through the Democratic Party. Indeed, from being considered a disenfranchised racial minority, the Irish eventually became part of the ethnic white majority population of the city.

Although most German immigrants in the nineteenth century moved to America for the same reason as the Irish—economic opportunity—they had very different origins. They tended to be highly skilled and were able to avoid poverty. From piano production and rubber manufacturing to finance, Germans dominated many high-income sectors of the New York City economic structure. Despite its comparative wealth, the German community in New York—called Kleindeutschland—became highly segregated from the rest of the population. This was partly the result of language differences, but it also reflected the reproduction of German institutions within the community.

THE NEW IMMIGRATION

The ethnic composition of immigrants to New York City changed drastically in the period from 1880 to 1920, when it shifted toward immigrants of southern and eastern European background. This immigrant wave, consisting of Italians, Russian Jews, Poles, and Greeks, among others, became known as the New Immigration. Many of these immigrants passed through the immigrant reception center at Ellis Island in the New York City harbor, which opened January 2, 1892.

Like many other mass migration movements, this one followed a chain migration process, by which the initial flow of migrants self-sustains and expands over time. The earlier immigrants sent information about employment opportunities back home, then provided social, economic, and cultural support to later migrants. Between 1880 and 1920, more than 4.1 million Italian immigrants arrived in the United States. Many of these stayed in New York City. Although only 14,000 Italian immigrants resided in New York City in 1880, by 1920 there were almost 400,000. Similarly, the city’s Russian Jewish immigrant community grew from 14,000 in 1880 to over half a million in 1920, becoming the largest foreign-born population.

The reasons for this mass migration episode are many. In the early nineteenth century, travel from Europe to the United States could take months. By the late nineteenth century, however, the growth of steamship and rail-road travel had made the global movement of people both faster and cheaper. Economic dislocations in southern and eastern Europe, particularly those associated with the decline of agriculture, had generated populations of workers eager to seek opportunities elsewhere. A large share of Italian immigrants, for example, came from southern Italy, especially Sicily and the Mezzogiorno, regions that had stagnated relative to north. Many of these immigrants were unskilled and obtained relatively low-paying jobs in America, including construction (for men) and the garment industry (for women). The mass migration of Russian—and other—Jews to America in the period from 1880 to 1920 was triggered not just by economic forces but also by the resurgence of anti-Semitism, pogroms, and other restrictive laws in many parts of central and eastern Europe. This led them to seek refuge in America. Many of these migrants were skilled workers who became artisans, craftsmen, traders, and financiers.

The late 1920s saw immigration to New York City decline sharply. One reason was the Great Depression, which started in 1929 and lasted through the 1930s. In New York City, unemployment rates reached as high as 25 percent, discouraging potential migrants from moving to America. But economic distress was not the only reason for the drop in immigration. Until the 1920s, the United States had virtually no immigration restrictions. Although border checkpoints had been introduced at twenty-four seaports and popular border crossings such as Ellis Island beginning in the early 1890s, the only restrictions were to exclude sick persons, known criminals, and the like. The
one country that faced sharp restrictions was China; the
1882 Chinese Exclusion and Immigration Act effectively
barred Chinese immigration until the 1940s. But the
Immigration and Naturalization Act of 1924 ended this
lax immigration policy. The law imposed the first perma-
nent quotas on immigration, although Western Hemi-
sphere migrants were exempted. It also created a system of
immigration preferences that gave an advantage to west-
ern and northern Europe. The 1930s saw further restric-
tive immigration policy initiatives; immigrants were seen
as taking jobs from Americans in a period of severe unem-
ployment.

ASSIMILATION

Immigration began to rebound in the 1940s and 1950s,
and it surged again after 1965. In that year, legislation that
repealed the quota system established in the 1920s was
signed into law. The result was a sharp increase in immi-
gration, especially from developing nations. The propor-
tion of New Yorkers born outside the United States had
dropped from 34 percent in 1924 to a low of 18 percent
in 1970, but by 2000 the proportion had risen back to 36
percent. Most of these immigrants were not from Europe
but from Latin America, the Caribbean, and Asia. Out of
the 2.871,032 immigrants counted by the 2000 U.S.
Census of Population, 53 percent were born in Latin
America and the Caribbean and 24 percent in Asia. Table
1 shows the population of the largest immigrant groups in
2000. The countries of origin where the largest number of
immigrants originated were the Dominican Republic,
China, Jamaica, Mexico, and Guyana. Most of these
migrants had an economic reason for moving to the city,
motivated by huge wage differences between their home
countries and a New York City economy that has dis-
played renewed and resilient strength since the early
1980s. Indeed, recent immigrants have generally been
able to raise their families’ standard of living, sending bil-
lions of dollars back to their home countries in the form
of remittances. But their social and economic progress in
the United States has not been without challenges.

Assimilation refers to the process of absorption or
fusion of immigrant groups and their descendants into
American culture or society. Robert E. Park and the
Chicago school of sociology were among the first social
scientists to study the process of assimilation in Chicago,
New York, and other cities, beginning in the 1920s. Their
analysis suggested that for the European immigrant
groups entering America in the late nineteenth and early
twentieth centuries, assimilation did gradually occur over
time. From the acquisition of English to a successful
accommodation to the labor market, the immigrants and
their descendants (second and third generations) were
becoming an integral part of American civil society.
This became known as the melting pot view of American
society.

But concern has been expressed by some social scien-
tists about the process of assimilation of recent immi-
grants, particularly those from Latin America and the
Caribbean. For instance, political scientist Samuel P.
Huntington, in his book *Who Are We? The Challenges to
American Cultural Identity* (2004), claims that, unlike pre-
vious immigration flows, recent immigrants from Latin
America and the Caribbean have not assimilated into
mainstream American society. Other social scientists have
also expressed concerns that recent immigrants may face
difficulties assimilating to the American labor market.
The evidence on these issues is not clear-cut.

CHALLENGES FOR IMMIGRANTS

Recent New York City immigrants struggle in an economy that is increasingly unequal and that rewards skills and schooling above anything else. For immigrants from Latin America and the Caribbean, whose level of schooling is substantially below the average, this leads to comparatively low income levels and high poverty rates. Table 1 displays basic indicators of socioeconomic status for various New York City populations. The data are from the 2000 U.S. Census of Population. As can be seen, the annual income per person in the average New York City household was $24,010. But for Dominican migrants, the largest immigrant group in the city, the average income per capita of $10,417 was less than half the average for the city and less than one-third the income per capita of the white population. Poverty rates among immigrants also tend to be higher than among the overall city population. For example, according to the 2000 census, about 30 percent of both Dominican and Mexican immigrants in New York had income below the poverty line, much higher than the citywide poverty rate of approximately 20 percent. The struggle of immigrants in and around New York City is poignantly portrayed by Dominican writer Junot Diaz in his novel Drown (1996).

Table 1 shows that the lower socioeconomic status of New York immigrants is not linked to high unemployment. The unemployment rates among immigrants are not that different from those of other New Yorkers. But wages are much lower, an outcome connected in part to lower educational attainment. As Table 1 depicts, the percentage of immigrants twenty-five years of age or older who had not completed a high school education in 2000 was much higher than for the rest of the city's population; for Dominicans it was 56 percent, more than twice the average citywide.

Some recent immigrants are also undocumented workers and face even more serious socioeconomic challenges. Estimates for 2005 suggest that as many as 10 million undocumented workers may be residing in the United States, with half a million in the New York City area. Recent immigration policy initiatives have led to more stringent U.S. immigration enforcement efforts, especially after the September 11, 2001, World Trade Center attacks. As a consequence, many undocumented workers—whether from China, Mexico, or Ecuador—are forced further underground, fearing deportation after many years of residence in the country. Entry into the United States from many developing countries has also become much tougher for both documented and undocumented immigrants.

But the social and economic struggles of the new immigrants are not new. Unskilled immigrants have historically struggled in the New York City economy. Even social scientists who proposed the melting pot theory noted that immigrant assimilation took several generations and that immigrants themselves often remained embedded in ethnic enclaves with limited linguistic, political, and economic incorporation into American society, whether in the form of a Kleindeutschland or a barrio. Some find that America, particularly urban America, was not and probably never will be culturally homogenous. For instance, Nathan Glazer and Daniel Patrick Moynihan concluded in Beyond the Melting Pot (1963) that in New York City cultural diversity and ethnic identity remain even after many generations, a conclusion shared more recently by sociologists Victor Nee and Richard Alba. At the same time, some immigrant groups have historically been able to make the transition from being marginalized racial and ethnic minorities to being considered as part of the country's majority white population while others have not. Social scientists such as Milton M. Gordon and John Ogbu have argued that discrimination and social exclusion may delay or permanently stall any processes of assimilation of stigmatized immigrant groups. The "racialization" of these immigrants may not, however, run along simple black-white racial lines. As sociologists Jennifer Hochschild, Clara Rodriguez, and Mary Waters have noted recently, racial formation for recent immigrants may evolve complex constructions, involving perhaps multiple racial identities. In addition, the recent waves of migrants to New York City include many who move back and forth between their source countries and the United States. This transnationalization, which makes the new immigration different from the old European immigration waves of the nineteenth and early twentieth centuries, generates new opportunities but also challenges for the migrants. Sociologists Hector Cordero-Guzman, Robert C. Smith, and Ramon Grosfoguel summarize these issues and discuss the work of the authors mentioned above in their edited volume Migration, Transnationalization, and Race in a Changing New York (2001).

National opinion surveys suggest that most recent immigrant groups and their children, including those from Latin America and the Caribbean, wish to succeed in American society in a way similar to their earlier cohorts. As in the past, despite serious challenges, many immigrants remain the strongest advocates of the American Dream. Sharply improved standards of living relative to the situation in source countries, as well as positive expectations of future economic progress and social mobility, are behind these opinions. But various populations in the United States—from blacks and Chinese to Puerto Ricans and Mexicans—have faced severe and persistent barriers to their socioeconomic progress. Recent immigrants are not immune from these forces, and they are well aware of the difficulties. For instance, the 2003 Pew Hispanic
Center National Survey of Latinos found that over 90 percent of immigrants from Latin America and the Caribbean believe that it is very important (for most, essential) that their children receive a college education in order to succeed in American society. But the same survey found that these immigrants are also seriously concerned about the quality of the high schools their children attend, the rising cost of college tuition, and similar issues.

Particularly worrisome is the condition of undocumented immigrants. In 2006, tens of millions of undocumented immigrants and other concerned groups peacefully marched in New York City, Los Angeles, and many other cities to encourage policy makers to adopt policies that will allow the immigrants to emerge from the underground labor markets in which they work. As in the past, appropriate economic, social, and immigration policies that facilitate immigrant socioeconomic mobility will be required to ensure that the new immigrants achieve their goals.

**IMMIGRANTS TO NORTH AMERICA**

An immigrant is a migrant who crosses an international boundary in the process of entering a new country and eventually establishing residence there. Immigrants differ from tourists because they eventually settle in the foreign country, whereas tourists eventually return home without establishing any settlement. The individual does not have to enter the country with the intention of settling, nor does the individual have to permanently settle. In some cases the migrant may move back and forth between one or more countries and the home country. Although in this case the migration is not permanent, the individual is considered a migrant. In contrast, an emigrant is a migrant who crosses an international boundary in the process of leaving a country with the intention of establishing residence elsewhere. A person who crosses an international boundary and enters a new country without establishing a new residence is a tourist or a visitor.

In every international migration, a migrant is simultaneously an immigrant and an emigrant. A key element in the definition of an immigrant is the establishment of a permanent residence in the new country. This usually means residence in the country of destination of at least one year, and is referred to as "long-term immigration." The number of long-term immigrants in the world has increased steadily in recent decades, from 75 million in 1965, to 120 million in 1990 (Martin 2001), to 190 million in 2006 (United Nations 2006). Approximately 3 percent of the world's population in 2006 was composed of long-term immigrants.

The motivations for immigration vary, but the most common is economic. Migrating for economic reasons is particularly important for persons moving from less developed countries to more developed countries (defined as all the countries of Europe and North America, plus the countries of Australia, New Zealand, and Japan). Most
immigration is to the more developed countries. Of the 190 million long-term immigrants in the world in 2006, 115 million resided in more developed countries (United Nations 2006).

Regarding the net gain or loss of international migrants, between 1995 and 2000 the United States had a net gain (immigrants minus emigrants) of more than 6.2 million immigrants, far surpassing the nearly 2 million net gain received by Rwanda, the country with the second-largest number. China experienced the largest net loss of immigrants during the period 1995 to 2000, with almost 2 million more emigrants than immigrants. Mexico had the second-highest net loss, more than 1.5 million more emigrants than immigrants (United Nations 2003).

CROSS-NATIONAL PERSPECTIVES
There are push and pull conditions facilitating migration in all countries of the world. In order for an individual or group to decide to migrate there typically needs to be a “push” from the mother country and/or a “pull” to the receiving country. These factors can be occupational, financial, or a variety of personal reasons. Other than these individual factors that encourage immigration, there are also contextual factors that pull migrants to the receiving countries. Once in these countries many migrants are pulled into so-called ethnic enclaves (Borjas and Tienda 1987). Such communities help individuals transition into life as immigrants by providing support and environments much like those in their mother countries.

Migration is most likely to happen between countries that are geographically close together. For the United States this means that most immigration comes from Mexico and Central America, due to proximity. Recently, however, a large number of migrants have come to the United States from China. Even though China is geographically distant from the United States, making migration difficult and expensive, the push and pull factors of China and the United States are strong.

THE AMERICAN IMMIGRANT
More than 98 percent of the residents of the United States are immigrants or the descendants of immigrants. In the United States in 2000, only 4.3 million people, or 1.5 percent, identified themselves as American Indians or Alaska Natives (Ogunwole 2006). Native Americans and Alaska Natives have resided in North America for as many as 40,000 years before the arrival of the first immigrants. They populated areas throughout North and South America, and many coexisted with European settlers until the eighteenth century, when most were eliminated through either disease or war. These conflicts continued through the late 1800s, when only a fraction of Native Americans remained (Purcell 1995).

In 1598 Spanish settlers first came to the United States for the purpose of colonization. They exploited the land and the indigenous peoples, but differed from earlier explorers in that most remained permanently in the United States. They settled mainly in the present-day southwestern United States and throughout Florida (Purcell 1995).

The first major influx of European immigrants to the United States was from England, with settlement mainly along the east coast in the present state of Virginia (Purcell 1995). The first permanent English settlement was Jamestown in Virginia, established in 1607. These early immigrants mainly lived off the profits from tobacco crops. Tobacco proved to be a profitable but labor-intensive pursuit and eventually spearheaded the immigration of British indentured servants and African slaves. Indentured servants usually came voluntarily to escape the economic downturns in England. The landing of the pilgrims on Plymouth Rock in 1620 marked the beginning of a great influx of English migrants who came to settle in the New World for religious freedom (Purcell 1995). These early immigrant groups “of the 1600s and 1700s established the basic context of American society. English was the dominant language in America; English legal and government documents were the norm; and culture was for two centuries copied after English literature, drama, and art” (Purcell 1995, p. 5). This early British model of American society would serve as the basis for future discrimination and exclusion of some immigrants over the next two centuries.

The forced migration of hundreds of thousands of Africans as slaves also occurred during this period. The first African slaves in the United States were purchased in Jamestown in 1619. This initial forced migration of Africans included only twenty persons, and the slavery of Africans was slow to develop in the colonies because of the use of Native Americans and white indentured servants for slave labor. However, by 1690 there were more African slaves in the United States than white indentured servants (Purcell 1995). The exploitation of African slaves in early America enabled the United States to compete in and eventually dominate the world market. The slave trade ended in 1807, but slavery persisted in the United States until the end of the Civil War (1861–1865). However, the system of racism upon which slavery was founded is engrained in the United States and remains a hurdle for African Americans and other racial and ethnic minorities in the United States.

The Dutch came to America in the 1600s and claimed much of present-day New York (Purcell 1995). Swedish immigrants also came to the New World during
this era, but were less successful than the British and Dutch settlers. These early European settlers created a stable life in America, which eased the immigration of others from Europe.

Scotch-Irish immigrants came to America for economic reasons and settled mainly in Pennsylvania. The seventeenth century also saw an influx of German immigrants who were largely motivated by war in Germany. The Germans were the largest non-British and non-English-speaking immigrant group to come to America, and they retained much of their culture. These cultural differences made the Germans one of the first European immigrant groups to experience discrimination from earlier settlers.

Before 1830 the contribution of immigration to population growth in the United States was small. Between 1821 and 1825, for example, the average number of immigrants every year was only about 8,000. This figure increased to almost 21,000 between 1826 and 1830. From 1841 to 1845 immigrants to the United States each year numbered more than 86,000. In the eight years between 1850 and 1857, the total number of immigrants to the United States was 2.2 million. In sum, between 1790 and 1860 the total number of immigrants to the United States was almost 5 million, and most of these were from Europe (Taeuber and Taeuber 1958).

The combination of pro-immigration campaigns and the reduced cost and ease of transcontinental transportation increased immigration drastically during this period. There was a second influx of German and Irish immigrants. German immigrants came to the United States and found work in established industry, aiding in the overall development of U.S. commerce. Irish immigrants, mostly Catholics, suffered severe discrimination that reached a peak in the mid-1850s with the emergence of the Know-Nothings, an anti-Catholic organization dedicated to maintaining the dominance of the United States of Anglo-Saxon Protestants. The end of the nineteenth century also saw immigration from Scandinavian countries. These immigrants sought land for farming and developed the mostly unsettled Midwest.

Chinese first entered the United States shortly after the beginnings of the California Gold Rush in 1849. An estimated 288,000 Chinese entered the United States during this period, although many returned to China before 1882 (Black 1963). Like most immigrants, the Chinese first came to the United States as laborers in search of work and wages. The port of entry for most Chinese immigrants during this first period was San Francisco, and to this day the Chinese name for San Francisco is Jiu Jin Shan, or “Old Gold Mountain.” The Chinese were subjected to hostile discrimination because many American workers were threatened by the low wages the Chinese were willing to take. With the passing of the Chinese Exclusion Act of 1882, Chinese immigration tapered off, eventually halting by the end of the twentieth century (Pedraza and Rumbaut 1996).

Overlapping with early Chinese immigration was increased immigration from eastern and southern Europe. These immigrants were not as welcome as the previous European immigrants because the “old” immigrants thought these “new” immigrants would take their jobs (Purcell 1995). The “new” immigrants were Italians, Greeks, Poles, and Slavs who spoke different languages and had slightly different physical features than western Europeans. They were subjected to discrimination, but were able to assimilate into white American culture with passing generations.

Currently the largest numbers of immigrants to the United States are from Asia and Mexico. These immigrants come to the United States for many of the same reasons the European immigrants came in earlier years. Population booms and increased industrialization combined with the economic opportunities of the United States created the push and pull factors that increased emigration from Asia. The Asian immigrants are able to move into ethnic enclaves where they find jobs and homes among people from their countries of origin. They are often criticized for not assimilating into “mainstream” white American culture (Portes and Rumbaut 1990).

The end of the twentieth century to the beginning of the twenty-first century has seen the immigration of millions of Mexicans to the United States. Like many newcomers to the United States, Mexicans come to find work and higher wages. Mexican migrants are subjected to the same discrimination as earlier immigrants groups (Hay 2001). Americans of Mexican descent vary in their levels of assimilation, based mostly on how long they or their forebears have been in the United States.

IMMIGRATION POLICY

Immigration was not a concern in early America, and no laws or policies regulated it on a national level, but the new U.S. Constitution did deal with the issue of naturalization, that is, the process by which an individual becomes a citizen (Purcell 1995). The Articles of Confederation allowed aliens to naturalize as American citizens after two years in the United States, something that was not previously allowed under British rule (Gabaccia 2002). These policies, however, did not apply to white indentured servants or to blacks. This was especially reflected in the Aliens Acts of 1798, which required aliens to register and allowed the president to deport any individuals deemed dangerous. The laws expired in 1801 when Thomas Jefferson took office, and the citizenship waiting period increased to five years (Purcell 1995).
Restrictions on certain groups based on race, ethnicity, or national identity continue to influence immigration policy in the United States even today.

One of the most notable laws restricting immigration to the United States was the Chinese Exclusion Act of May 6, 1882, which reflected the public concern about the large numbers of Chinese who had come to the United States to provide inexpensive labor for the construction of the transcontinental railroad. This law suspended the immigration of Chinese laborers for ten years; permitted Chinese who were in the United States as of November 17, 1880, to stay, travel abroad, and return; prohibited the naturalization of Chinese; and created the so-called “Section 6 exempt status” for Chinese teachers, students, merchants, and travelers, who were admitted on the presentation of certificates from the Chinese government.

The next significant exclusionary legislation was the Act to Prohibit the Coming of Chinese Persons into the United States of May 1892, better known as the Geary Act. It allowed Chinese laborers to travel to China and reenter the United States, but its provisions were otherwise more restrictive than preceding immigration laws. The Geary Act required Chinese to register and to secure a certificate as proof of their right to be in the United States; those who failed to do so could be put into prison or deported. Other restrictive immigration acts affecting citizens of Chinese ancestry followed (King and Locke 1980). The Chinese Exclusion Act and later exclusionary laws were the first to use the concept of an “illegal alien” (Pedraza and Rumbaut 1996).

The next major policy relating to immigrants was the Immigration Act passed in 1917 that increased the head tax on immigrants to $8.00 and required incoming immigrants to pass literacy tests. The Immigration Act also “established several new categories for exclusion, including vagrants, alcoholics, and the psychopathically inferior” (Purcell 1995, p. 82). This law required the potential immigrant to be able to read a passage in English or another language. It also extended the exclusion of Chinese and Japanese to all Asians.

In 1921 further restrictions were passed setting quotas based on nation of origin. In 1924 Congress took this one step further by passing the National Origins Act, which restricted the total number of immigrants to 150,000; the division of the quotas reflected the American population enumerated in the 1890 census. This was done in an effort to restrict immigration mainly to those from Great Britain, Scandinavia, and Germany while reducing immigration from all Asian countries and severely restricting the immigration of Italians, Slavs, Jews, Greeks, and other southern and eastern Europeans (Purcell 1995).

From the 1920s to the 1950s immigration in the United States changed. The Great Depression and World War II (1939–1945) ushered in a period of slow, and sometimes negative immigration, resulting in a net loss. The only significant immigration was from Mexico under the Bracero Program, which admitted Mexican male workers while Americans were overseas. In 1952 the Immigration and Naturalization Act was passed, maintaining most of the quotas set forth by the National Origins Act of 1924 (Hay 2001).

The next major law regarding immigration policy was the Immigration and Naturalization Act of 1965, which became law in 1968. This act ended the national origins quota and allowed the immigration of family members of those already living in the United States, as well as individuals in certain occupations. It also ended the restrictions on Asian immigration and limited immigration from the Western Hemisphere as a whole to 120,000 (Hay 2001). The change in law produced an influx of immigrants from previously unrepresented countries such as many in Southeast Asia and the Middle East.

EXPERIENCES OF IMMIGRANTS

Immigrants have been subjected to discrimination from individuals and from institutions in the United States (Feagin and Eckberg 1980) that have limited their access to the means of success in the United States. “Because patterns of discrimination—individual and institutional—served to exclude some groups from full participation in the society, their access to the historical moments of opportunity that presented themselves over time also varied” (Pedraza and Rumbaut 1996, p. 17). The experiences of discrimination that immigrants have endured vary by race, ethnicity, nationality, and time of immigration.

Assimilation is the process by which individuals become a part of the greater American culture. In order to succeed in America, common thought has dictated that individuals must assimilate into the dominant culture, thought to be composed of white, Protestant individuals of European descent. Cultural pluralism, or multiculturalism (Gordon 1964), the accepted notion of assimilation in the United States today, entails that all groups retain their uniqueness but come together to form a diverse and distinct American culture. However, immigrants are not given the same opportunities to assimilate based on their ethnicity, race, or the circumstances surrounding their immigration. In the early centuries of the United States, assimilation into white dominant culture was an easier task because of the racial, ethnic, and national similarities that were shared among immigrants from Europe. Their transitions into the dominant culture were not necessarily effortless or quick, but were less difficult than those of later generations of foreign immigrants.

In many ways, immigration to the Americas introduced the concept of whiteness and what it meant to be
Immigrants to North America
cated individuals. In 2006 laws were proposed to stop and control undocumented immigration, mostly from Mexico. The study of immigration shows clearly the undeniable role that immigration has had on America and American culture. The contribution of immigrants is a major foundation of the United States and will continue to be important in every aspect of American life.

IMMIGRATION

Immigration studies have yet to reach a consensus on which kinds of human movements constitute immigration. This entry uses the term in its broadest sense, referring to people's temporary or permanent movements and geographic relocation or displacement across political boundaries.

INTERNATIONAL IMMIGRATION

Throughout history, immigration has been an important social force shaped by the world as well as shaping it. In Global Transformations (1998), David Held et al. delineate three phases of migration: premodern, modern, and contemporary migration. In the premodern societies, mass migration was instrumental to the formation of states, particularly in Asia but also in other parts of the world. Modern migration started from the fifteenth century and occurred in three major immigrant flows: (1) European settlers, or the first mass migrants, primarily sponsored by the states, to North America; (2) chattel slaves from Africa to North America, the largest forced migration in human history; and (3) indentured Asian laborers, or the coolie system, which replaced chattel slavery in the latter half of the nineteenth century. Contemporary migration is said to have started after World War II (1939–1945). In the contemporary era, major migration flows were not only to North America but also to Europe, Australasia, and the Middle East. Among the immigrant populations of the contemporary era were increasing numbers of refugees as a result of wars, localized poverty, and political persecution.

Many scholars, including Joaquin Arango (2004) and Stephen Castles and Mark J. Miller (2003), also note that immigration since the 1970s has taken on distinct features. First, nation-states have exercised more control over immigration, drawing an increasingly more pronounced line between desired and undesired immigrants. On the one hand, there is state-engineered competition for skilled labor, particularly among traditional destination countries such as Australia, Canada, and the United States. On the other hand, border controls, mainly directed at immigrants deemed illegal, have been intensified. Despite the increased border control, however, human trafficking has become more salient. The second character of the latest immigration movements is the increasing number of actors shaping immigration flows. Attempts to manage international immigration have been coming from different levels of society, ranging from transnational immigrant communities to the United Nations. The third feature of the current migration trends is the changing demography of immigrants. Asians, Africans, and Latin Americans have gradually replaced the Europeans as the major immigrant population. In addition, the gendered composition of immigrants has changed. Women now account for around 50 percent of the total immigrant population. As well, more women than before move as independent immigrants. Whereas this change remains merely a statistical fact to many scholars, it has compelled others to try to bring women back into the history of immigration, which has largely been written in a gender-neutral or genderless tradition. A good example is the book Women, Gender, and Labour Migration: Historical and Global Perspectives (2001), edited by Pamela Sharpe, which offers perspectives on immigration that take gender into account.

THEORIZING IMMIGRATION

The complex social phenomenon of human movements has spurred much theorizing about the causes and consequences of immigration. The three major theoretical approaches informing immigrant studies are the economic equilibrium approach, the historical-structural approach, and the migration system theory.

The economic equilibrium approach, also known as the push-and-pull theory, is the dominant perspective in the literature of immigrant studies, according to Castles and Miller. The major tenet of this approach is that immigration is the summation of human agency and an outcome of people's rational cost-and-benefit calculations. Factors pushing immigrants to leave typically include poverty and political repression; factors pulling immigrants away from their origins are often better economic opportunities and political freedom. George Borjas (1989) presents a modern version of the equilibrium approach. He proposes a conception of an immigrant market wherein immigrants, instead of commodities, are exchanged. According to Borjas, individual people are "utility maximizers" responsive to the call of an immigrant market. That is, immigration is regarded as a mechanism through which an optimum distribution of land, labor, capital, and natural resources can be achieved and the social-economic equilibrium of different places can be established.

Whereas the equilibrium approach takes individuals' decisions as its units of analysis, the historical-structural approach locates the reasons and results of immigration in the macroeconomic and political structures of the world. As Castles and Miller point out, this approach is informed by Marxist political economy and the world system theory. It posits that contemporary immigration is a social process that mobilizes cheap labor for capital and thereby helps to sustain the capitalist mode of production in the era of globalization. From the perspective of the world system theory, immigration is considered a new link between developed and developing nations, which were previously connected through colonial occupation or other forms of domination. As the new link, immigration perpetuates the asymmetrical power relationship between the two.
The migration system theory is an attempt to capture all factors affecting the movements of people. A migration system is constituted by two or more countries involved in people's movements. This theory directs researchers' attention to the micro, macro, and meso aspects of migration, as well as historical conditions contributing to migration. Similar to the historical-structural approach, it suggests that prior links between immigrant sending and receiving countries, such as colonial domination, military occupation, trade, and investment, all help to lead to people's migration movements between these countries. At the macro level, international relations, interstate relations, and immigration and other state policies are important incentives or disincentives to migration. At the meso level, the migration system theory is interested in the roles of individuals, groups, or institutions that mediate people's movements. At the micro level, the theory addresses informal networks such as family and community connections that facilitate immigration. In recent years, the new links between transnational communities, in particular, have given rise to a new area of study on transnationalism, according to Castles and Miller.

CRITIQUE OF IMMIGRATION
THEORIES AND FUTURE DIRECTIONS OF RESEARCH

While insightful, each of the approaches proposed has significant limitations. A major critique of the equilibrium approach comes from Charles Wood (1982). Wood points out that, first of all, immigration movement has not brought about the anticipated social-economic equilibrium. Rather, recent decades have witnessed increased disparities in regional development. Second, the ahistorical nature of the approach is problematic. The notion of a free market, on which the whole approach is based, is not the empirical truth in all societies at all historical moments. Finally, with a sole focus on micro-level decision making, this approach misses the large social conditions conducive to the movements of people.

In contrast, the historical-structural approach is mainly criticized for failing to explain how the immigration decision comes about for individual actors, as discussed by Wood and also by Castles and Miller. As well, the consequences of immigration as proposed in the historical-structural approach are uni-dimensional and deterministic. Movements of people may not necessarily lead to deprivation in one country and capitalization in the other. Immigrants may bring multiple effects on both the sending and receiving countries. The central problem with this approach is that it reduces people to labor caught up in the capitalization process on a global scale, rather than treating them as human beings with diverse needs and interests.

Epistemologically, the above two approaches are distinct from each other; whereas the former is functionalist in nature, seeing immigration as a means to social harmony, the latter construes immigration as a force adding to social inequalities and conflicts. Despite the differences, there is no doubt that both approaches illuminate some facets of immigration while disregarding others. For instance, neither of them has addressed the facilities and material conditions that contribute to or contain the movements of people. The migration system theory is advantageous to the others in that it focuses on all key dimensions of immigration. However, despite its promise for a holistic understanding of immigration, the migration system theory does not offer a means of interpretation.

In addition to the problems associated with each approach, there are significant issues related to how the phenomenon of immigration is approached in general. First of all, immigration is often considered an aberration that needs to be corrected or a problem that needs to be addressed. The fact that immigration is an integral part of human history has not been registered in the conceptual underpinning of studies on immigration. Second, studies tend to focus on why people move instead of why few people move or why the majority of human populations are not free to move, according to Arango. Posing the alternative questions makes it necessary to critically consider the roles that nation-states play in controlling or restraining people's movements, which have yet to be deeply interrogated. Third, immigration studies mainly center on labor migration. Refugees and the so-called illegal and undesired immigrants remain at the margin of immigrant research. Finally, while immigration studies have started to address the issue of gender, insufficient attention has been paid to how the increasing presence of immigrant women engenders political, economic, and cultural changes in both sending and receiving countries.

Immiserizing Growth

Immiserizing growth occurs if a technological improvement or an increase in the availability of a factor of production makes people more miserable in that it actually decreases the real output of an economy. It is often modeled as occurring because of structural rigidities in a model with international trade. Early exceptions, where immiserizing growth had domestic causes, come from classical and, perhaps, Marxist theories (Marx 1863–1883). David Ricardo (1817) introduced this possibility in a chapter entitled “On Machinery” that he added to his last edition of *The Principles of Political Economy and Taxation*. He provided an example where a technological improvement would reduce equilibrium output in the short run. In the long run, however, real output would rise (see Hicks 1969; Samuelson 1988; Shields 1989). Marx also discussed the possibility of economic crises brought on by a falling rate of profits and a rising rate of exploitation (see Shaikh and Tonak 1994).

In the neoclassical tradition, immiserizing growth is seen as a result of either policy distortions or market failures. The policy distortions might be domestic distortions such as distorted factor prices (Bhagwati 1969) or trade distortions such as tariffs (Johnson 1967). The most discussed possibility of immiserizing growth, both in the short run and in the long run, was developed and discussed by Jagdish Bhagwati (1969). It involves a decrease in the country’s terms of trade resulting from this growth, which is of sufficient magnitude to reduce the country’s real income. A country will export goods using its abundant factor. If the supply of this factor increases, the country will produce and export more of these export goods and produce less of other goods (the Rybczynski Theorem). Immiserizing growth can occur if this expansion in exports causes the prices for the country’s export goods to deteriorate enough to make it worse off with the increase in production. Whether or not a country might be likely to suffer from immiserizing growth depends on three conditions. First, the country must be driven to export. Second, changes in these exports need to have a large impact on the good’s price, and the foreign demand for these exports needs to be inelastic so that a rise in exports leads to a decline in export earnings. Third, the country must be highly dependent on exports, and exports must be a high proportion of gross national product.

The export pessimism underlying the concept of immiserizing growth is an extreme form of the pessimism behind the structuralism of Raúl Prebisch (1964) and others. It implies some unlikely behavior of the exporting country. It implies no endogenous reaction to these declining terms of trade (Clarete and Whalley 1994). To see why this type of immiserizing growth is unlikely to occur, consider the situation of the major oil exporters such as Saudi Arabia and Kuwait. They seem to satisfy the conditions for immiserizing growth. They are clearly driven to export oil, as it dominates the economies of these countries. In addition, the countries are sufficiently important as suppliers that an increase in their exports will drive oil prices down. Since the demand for oil is highly inelastic, this increase in supply would dramatically reduce oil revenues. However, long-term immiserizing growth seems unlikely for these countries.

The very reason immiserizing growth may be unlikely for these countries is the very reason it is such a threat. It would be foolish for any supplier to do nothing in the face of dramatically declining terms of trade. The inelasticity of demand provides an incentive for suppliers to exercise monopoly power and to try to organize other suppliers into a cartel. Indeed this is what happened with the formation of the Organization of Petroleum Exporting Countries (OPEC). Far from being competitive suppliers with no power to control prices, the major oil exporters, individually and collectively, have considerable price control. They did not dramatically increase production when prices were low in a desperate but fruitless attempt to increase declining revenues.
Structuralists such as Prebisch and neo-Marxists (see Prebisch 1964; Frank 1967) emphasize that growth for small, less developed countries might harm these countries even if the demand for their country’s exports is highly elastic. Collectively, they may be selling into a market with inelastic demand. While it may seem to be in the interest of each country to expand its exports, collectively they may drive the price down to an extent that immiserizing growth occurs.

IMPEACHMENT
Shortly before the House Judiciary Committee met in October 1973 to debate proposed articles impeaching President Richard Nixon (1913–1994), a then-unknown Democratic congresswoman from Texas momentarily caught the public’s attention. Barbara Jordan (1936–1996) announced that she felt bound to go to the U.S. National Archives to put her fingers on the constitutional text that delegated to the House of Representatives the power to vote articles of impeachment. To many, hearing Jordan's sonorous retelling of her experience, the impression must have been that by reading the constitutional language dealing with the impeachment and removal of “the President, Vice President and all civil Officers of the United States” (Art. I Sec. 2 (5), Sec. 3 (6–7); Art. II Sec. 2 (1), Sec. 4), Jordan would know exactly what the rules were that governed the process. In fact, the Constitution’s language on impeachment is as difficult to interpret as pharaoh’s dreams.

Impeachment dates to the thirteenth century. Those who would frame and ratify the U.S. Constitution were familiar with the process. In England, it allowed the king’s ministers to be punished even though the king himself could do no wrong. By the mid-eighteenth century, however, despite the publicity that attended the impeachment in 1787 of Warren Hastings (1732–1818), the first governor-general of British India, the process had pretty much disappeared. Hastings was charged with corruption during his tenure in India. His trial began in 1788; he was finally acquitted in 1795. It had never been transplanted to the colonies. In England, its decline paralleled the growth of ministerial responsibility to Parliament and the need of a ministry to have “the confidence of Parliament” and not simply the approbation of the monarch.

IMPEACHMENT IN AMERICA
Despite its rarity in contemporary England, both the Virginia and New Jersey plans provided for impeachment, although both gave the power to members of the judiciary. Only as the Constitutional Convention was winding down in 1787 was the power to impeach and remove vested in the House and Senate, with the chief justice of the Supreme Court involved as the presiding officer only at the trial of an impeached president. The Constitution also clearly distinguished how impeachment would be used in the United States as opposed to England by providing that conviction was limited to removal from office and possibly disqualification from holding public office in the future. In contrast, in England, Parliament could vote for criminal punishments, including death for those found guilty of “high crimes and misdemeanors.” The U.S. Constitution also explicitly limited the president of

Michael P. Shields
the United States from pardoning those impeached and convicted.

Although generally referred to as impeachment, the process has two distinct steps. The first involves impeachment, a task assigned to the House, where a simple majority vote is required to approve articles of impeachment. Persons impeached are then tried before the Senate, with the House designating the prosecutors. A two-thirds vote of the Senate is required for conviction. Two presidents—Andrew Johnson (1808–1875) and William Jefferson Clinton (1946)—have been impeached. Nixon resigned before the full House voted on the impeachment articles adopted by the Judiciary Committee.

More common have been impeachment proceedings against federal judges. Thirteen have been impeached; seven were convicted, four were acquitted, and two resigned with no further Senate action. One U.S. senator and one cabinet member were also impeached. Senator William Blount (1749–1800) of Tennessee was the first individual impeached. The Senate expelled Blount in 1797 and then voted that it did not have jurisdiction to vote on the impeachment articles. Blount was charged with seeking to incite Indians to assist the British in driving the Spanish from west Florida. U.S. Secretary of War William Belknap (1829–1890) resigned in 1876 after being impeached for receiving bribes; the Senate failed to muster the required two-thirds vote to convict.

**DISPUTED LANGUAGE**

Despite the number of times impeachment has been initiated there remains much controversy as to its exact parameters. Republican House Minority Leader (later president) Gerald Ford (1913–2006), in leading the effort to impeach Justice William O. Douglas (1898–1980) (Ford and fellow Republicans were concerned both about the Justice’s increasingly erratic lifestyle and the possibility that some of his business dealings were illegal), famously quipped that an impeachable offense was “whatever a majority of the House concludes it to be . . .; conviction results from whatever offense or offenses two-thirds of the other body considers to be sufficiently serious.” Given the continuing scholarly debate, Ford’s statement has much to recommend it. Among the debated issues is the nature of “high crimes and misdemeanors,” the famously imprecise language taken from British practice and enshrined by the Framers in the fourth section of Article II: whether Congress members can be impeached and whether judges can be removed for lack of “good behavior;” whether those removed can have recourse to judicial review; and, finally, whether there are other constitutionally permissible means by which officials can be removed from office.

One set of scholars argues that “high crimes” is limited to indictable offenses. This was argued by Richard Nixon’s attorney, James St. Clair (1920–2001), and by law professor Raoul Berger (1901–2000). In contrast, Michael Gerhardt (2000) claims this is too narrow a reading of the English precedents and would have meant for much of early American history that there were few if any grounds for impeachment, since there were few if any federal crimes for which an individual could be indicted. His argument is that the term embraces any activity that would threaten the nation or bring the office into grave disrepute.

Others have claimed that offenses must relate to the office the person holds. This view is generally rejected with the frequently cited example being that of a hypothetical public official who commits a murder totally unrelated to his or her public responsibilities.

Supporting the argument that the standard, particularly regarding presidents, should be high is the claim that removing a president should be a very rare occurrence, since in doing so the Congress would be setting aside the will of the people. Critics of the impeachment of President Clinton argue that this action was almost akin to a congressional coup d’état and that the underlying act, a tryst with a White House intern, was a purely private act. Supporters of the impeachment argue that Clinton’s grand jury perjury and his sullying of his office were more than sufficient to justify his removal and that his successor, Vice President Al Gore, had also been elected by the people, a situation quite unlike the nineteenth-century case of President Andrew Johnson.

The impeachment of Senator Blount can be used to argue both that members of Congress can be removed and that they cannot. The dominant view is that there is no basis to include members of Congress under the phrase “all civil Officers.”

The first official removed from office (Blount was expelled by the Senate, acting under its powers under Article I, section 5), John Pickering (1738–1805), a U.S. district court judge who was impeached in 1803, clearly committed no crime. He was probably mentally ill and frequently drunk. Like many subsequent impeachments, the vote was along party lines. Pickering’s impeachment leads some to argue that since judges serve “during good behavior” (referring to Article III, Section 1 of the Constitution, which concerns a judge’s life tenure), the fact of bad behavior on the part of judges constitutes additional grounds for removal. The weight of historical evidence is opposed to this position.

Very much in dispute is whether the Constitution allows Congress to fashion other means to remove officials, particularly someone like Pickering who commit no crime and whose behavior would not serve to bring the government into disrepute. The Senate has, since the 1930s, provided that the trial can be conducted by a com-
committee reporting to the full Senate. Several proposals have been advanced in Congress by which federal judges could be removed short of impeachment. The Twenty-fifth Amendment provides a means by which an incapacitated president can be removed. Whether a similar amendment to remove disabled judges is necessary or whether there can be a statutory solution is not clear.

Finally, impeachment appears to be one of the few issues that might fall within the steadily shrinking orbit of nonjusticiable “political questions.” In a case arising from the 1989 impeachment for perjury of Judge Walter Nixon Jr., the Supreme Court, by dismissing his appeal, appeared to indicate that judicial review, after conviction, was not an option. However, like nearly every other aspect of the impeachment process, this statement too is subject to dispute.

IMPERIALISM

Imperialism as a distinct set of ideas can be traced to the second half of the nineteenth century; it refers primarily to a political system based on colonies governed from an imperial metropolitan center for direct or indirect economic benefit. Commonly associated with the policy of direct extension of sovereignty and dominion over non-contiguous and often distant overseas territories, it also denotes indirect political or economic control of powerful states over weaker peoples. Regarded also as a doctrine based on the use of deliberate force, imperialism has been subject to moral censure by its critics, and thus the term is frequently used in international propaganda as a pejorative for expansionist and aggressive foreign policy.

IMPERIALISM IN THE NINETEENTH CENTURY

Although the term empire (Latin: imperium), inhering in the idea of supreme command or authority, is regarded as part of a universal human political experience since the rise of polities in antiquity, imperialism is more narrowly dated to the era of colonial empires of the eighteenth and nineteenth centuries. During this era the economic and military advantages of mercantile, industrialist, and capitalist countries were translated into a more or less systematic and formal policy of conquest, annexation, and administration of the world outside of Europe and the Americas. Between 1880 and 1914 much of this world was partitioned in territories under the direct rule of European countries, or subjected to their political influence. Led by Great Britain, France, Germany, the Netherlands, Belgium, and the United States, and later followed by Russia and Japan, principal powers of the world divided Asia into informal zones of influence, and carved up the Pacific and Africa into new territorial, and mostly colonial, units. The expectation of asymmetrical and iniquitous distribution of political-economic gains was complemented by the roughly contemporaneous idea that the world was inhabited by advanced and backward races and nations, and that imperial expansion was also in part the preponderance of those who were fit and thus destined to rule. In the 1890s many contemporary observers associated imperial expansionism with a new phase in the development of international capitalism, one that succeeded the era of free competition and economic liberalism of the mid-nineteenth century. This particular
use of the term *imperialism* has often been attributed to V. I. Lenin, the architect of the Russian Revolution. John A. Hobson (1858–1940) noted the heightened currency of the term in the late nineteenth century, both in political discussion and common speech. Whether they were influenced by Karl Marx’s theories or not, contemporaries were aware of the economic roots of this new version of imperial expansion, which they identified with the territorial division of the world among major European powers into formal or informal colonies and spheres of influence. Such claims among European military and economic rivals were nowhere more evident than at the Berlin Conference of 1884, hosted by the German chancellor Otto von Bismarck (1815–1898), who had come to the conclusion that an Africa divided along colonial lines by mutual agreement among the European empires would safeguard markets and raw materials. This move led to the proclamation of a number of protectorates and colonies, known as the “scramble for Africa,” and the eventual partition of the entire continent.

The ties between mercantile capital, empire-building, and colonial ventures had already been secured by the late eighteenth century. Capital invested in the triangular trade between England, Africa, and the Caribbean had a profound impact on New World Iberian colonies. The African slave trade, for example, provided the labor for Brazilian and Caribbean plantations that produced sugar for much of western Europe and North America. During the early nineteenth century, settler colonies were also becoming important, both commercially and politically, best articulated perhaps in the context of Upper and Lower Canada by John Lambton, Lord Durham (1792–1840) in his *Report on the Affairs of British North America* (1839). While drawing up the report he was ably assisted by Edward Gibbon Wakefield (1796–1862) and Charles Bulwer (1806–1848), both of whom were well known for their progressive and radical views on social reform. The Durham Report, which effectively safeguarded British influence over a divided Canada, advocated responsible government through graduated constitutional change, while at the same time recognizing the value of commerce and investment. It also delineated imperial trade and foreign policy, and the regulation of colonial settlement through a careful distribution of public lands by the British government.

Already by the 1840s colonies had assumed heightened importance as welcome outlets, not only for criminals and outcasts, but also for increasingly large numbers of migrants who could not secure adequate employment and resources in the mother country. There were many theorists and advocates of settler colonialism, among them the radical Wakefield, who called for a “systematic colonization” of the Australian continent, arguing that a successful transference depended on the compatibility of capital and labor, and economic opportunity to create harmony between the different classes of settlers. The absorption of “redundant people” in the colonies, Wakefield pointed out in his *View of the Art of Colonization* (1849), would result in increased supply of food and raw materials for manufacture for the inhabitants of the empire at home. Wakefield clearly anticipated the importance of empire for the accumulation of capital and investment overseas.

It was Bruno Bauer (1809–1882), the German philosopher, historian, and theologian, and also onetime leader of the left-Hegelians, who advanced the idea of imperialism as a powerful and disruptive global political force. The entry of Russia as a world power, he predicted, would usher in a new era of transnational imperial rivalry. According to Bauer, this was the result of the contradictions that had arisen between the demands of modern mass society and the political absolutism of the state, a symptom of the crisis of the old European liberal order (Bauer 1882). Thus, for example, in Bismarck’s model of state-based socialism in Germany, economic production was subjected to close political control, driven by the need to rein in the unruly forces of capitalism. In Benjamin Disraeli’s England, in contrast, political leaders sought a mass mandate for imperial policies in order to shore up and bolster a paternalist monarchy whose institutional basis had been eroded by the force of economic change. Bauer’s verged on an apocalyptic vision, portending heightened imperial rivalry across the world, resulting in a war among the leading nations.

Imperialism and nationalism had long been regarded as kindred forces. At the turn of the century, among theorists who challenged this commonly accepted idea was the British liberal economist John A. Hobson, who argued in his influential *Imperialism: A Study* (1902) that the drive for imperialist expansion in Europe could not be fully explained by the rise of patriotic nationalism. From the vantage point of an entire nation and its people, the policy of imperial expansion did not result in long-term and tangible economic benefits; the costs of wars of expansion far outweighed the returns, and indeed, necessary social reforms that would have benefited the economically disadvantaged sections of the population were often set aside in favor of imperial adventurism. Such policies, however, served the financial interests of capitalists and their representative political groups, who were, according to Hobson, custodians of the “imperial engine.” Periodic congestion of capital in manufacturing, resulting from uneven distribution of income, falling demand, and excess goods and capital inside a given nation-state, urged the search for investment outlets overseas, thus driving the search for new markets and opportunities for investment in foreign markets, including distant colonies and dependencies. This process was further propelled through
the practices of larger firms and financial groups operating in trusts and combines that sought restrictions on output in order to avert loss through overproduction. Hobson's study, which focused on business cycles, behavior of financial groups, and patterns of overseas investment, directly influenced Marxist thinkers in their analysis of imperialism.

IMPERIALISM AND ITS CRITICS: THE TWENTIETH CENTURY AND BEYOND

During the early decades of the twentieth century there were many radical critics on the Left who saw the rise of imperialism as a historical force intimately tied to the worldwide expansion and consolidation of finance capital. As Lenin in his introduction to Nikolai Bukharin's tract Imperialism and World Economy (1917 [1972]) noted succinctly: “The typical ruler of the world became finance capital, a power that is peculiarly mobile and flexible, particularly intertwined at home and internationally, peculiarly devoid of individuality and divorced from the immediate process of production, peculiarly easy to concentrate” (p. 11). Much of the debate centered on Marx's prediction about the concentration of capital. Rudolf Hilferding in Finance Capital (1910 [1981]) and Otto Bauer in Die Nationalitätenfrage und die Sozialdemokratie (The Nationalities Question and the Social Democracy, 1907), extending Marxian ideas of capital accumulation, argued that the sectors of banking and finance had increasingly started to exert pressure on industrial production, leading to the formation of monopolies and cartels, the quest for protection of markets, and ultimately to economic imperialism, international rivalry, and war. Similarly, Rosa Luxemburg, the Polish-born German revolutionary and founder of the Polish Social Democratic Party and the Spartacus League (which later became the German Communist Party), forcefully argued in her 1913 tract Die Akkumulation des Kapitals (The Accumulation of Capital) that imperialism was the direct result of the dynamic and aggressive inroad of capitalism into the less economically advanced parts of the world.

Bukharin and Lenin, stalwarts of Bolshevism and veterans of the October Revolution, took these ideas further, advancing that imperialism was not a contest for world domination among rival races such as Slavs and Teutons, but the direct result of a particular form of capitalism marked by the changing structure of financial investment and relations of production. Colonial expansion and imperial wars were indeed signs of a developing global economy. Bukharin saw the global expansion of finance capital as a historic phenomenon tied to new national rivalries, fiscal competition, and imperial conquest.

Lenin penned a small tract, “Imperialism: The Highest Stage of Capitalism” (1917 [1970]), which soon became one of the most influential of all Marxist studies on the subject. Lenin saw imperialism as closely tied to the normal functions of an advanced capitalism that had already undergone profound changes along with the development of modern European nation-states. More importantly, monopoly capitalism had already edged out an earlier form of competitive capitalism marked by the free entry and exit of small and large-scale industries and businesses. Toward the end of the nineteenth century, an advanced stage of capital was already in progress where open economic competition and production of commodities were replaced by predatory monopolies and cartels. For Lenin, a good example of this process was the changed role of banks as financial intermediaries to monopolistic interest groups, merging readily with industry and leading to the domination of finance capital and the unprecedented concentration of production. As a result, a fundamental and historic feature of capitalism had been altered: What was once characterized by the separation of ownership of capital from the process of production was now marked by a separation of finance capital from industrial capital. Lenin held that new finance capital had outpaced commodities in reaching far corners of the world, heightening actual divisions and rivalry between trading groups and nations. New segments of the world market were thus being appropriated by monopoly capital, with the merging of corporations—such as conglomerates in the oil industry—to weed out competition.

Lenin saw the division of the world among colonial and imperial powers as closely associated with the transformative power of finance capital. Thus the scramble among powerful nations for colonial expansion was largely fueled by the drive for raw materials and markets. Lenin famously proclaimed imperialism as the “highest stage” in the development of capitalism. As monopoly interest groups sought to divide the world into arenas of economic exploitation, they unleashed new rivalries over markets and raw materials among both advanced and less advanced capitalist nations. The uneven economic development of nations, including imperial and colonial powers, further intensified economic competition and political conflict.

Lenin was vehement in his opposition to other theorists of imperialism, especially his contemporary Karl Kautsky (1854–1938), one of the most influential voices among German Social Democrats before World War I. Kautsky in “Die Internationalität und der Krieg” (Imperialism and the War, 1914) argued that imperialism was indeed the logical outcome of capitalism, but was beset by its own fatal contradictions. Kautsky predicted that World War II would lead to the demise of imperialism as an international policy along with its global-indus-
trial order, and rather than a worldwide communist revolution, it would create a new and peaceful consortium among advanced nations along with a cosmopolitan global economy free of imperialistic militarism.

This theory—that political, military, and ideological aspects of imperialism during the late nineteenth and early twentieth centuries were essentially manifestations of deep-seated economic causes, especially the rise of monopolistic finance capital fueling the drive for overseas colonies and global markets—is often referred to as the “Lenin-Hobson thesis.” Although some of the basic premises of the thesis have been questioned in light of subsequent history—for instance, the relationship between militarism and economic gain and also between colonialism and the expansion of finance capital—aspects of it continue to be influential. Critics of Lenin and Hobson, and of Marxist theories of imperialism in general, question the assertion that wars of colonial expansion or imperial rivalry were fought for solely economic reasons and that capitalism was the primary engine of colonial and imperial expansion. Some have argued that imperialism was an ideology inherently antithetical to the logic of capitalism and market economy, and as such, a relic of the past; others have sought its origins in the rise of mass politics and fascism (Arendt [1951] (1973)).

More recently, historians following Ronald Robinson and John Gallagher (1961) have questioned the very premise that the high tide of imperialist expansion in the late nineteenth century was a new or unprecedented phenomenon, arguing instead for an extended period of free-trade imperialism bridging the era of mercantilist empires that developed during the fifteenth to the eighteenth centuries and the nineteenth-century wars of imperial annexation. In this intermediate stage, European political and commercial interests were extended through indirect means, without the administrative responsibility of direct colonial rule. Relying largely on the history of the British Empire in Asia and Africa and the expansion of British financial interests in Latin America, such critics view imperialism as a long-unfolding process in which imperial occupation and commercial exploitation are the results of long-term, informal economic relationships between European commercial agents and local regimes, which in themselves were active participants in the process of empire building. Such formulations underscore the role of political regimes that eventually succumbed to European empires, and their subjects who resisted or became unequal partners in colonial economic expansion. They also emphasize the vital role played by newly independent Latin American countries such as Argentina, Bolivia, and Chile as substantial markets, and as part of an extended informal empire (Hopkins 1994). These markets were crucial to British industrial production and finance capital in the late nineteenth and early twentieth centuries, and more generally to the global economy dominated by the United States and western Europe, without directly being part of the colonial system.

Despite such revisions, critics of imperialism still ascribe it to the direct or indirect manifestation of the march of global capitalism from the nineteenth century to the present. Sociologists such as Immanuel Wallerstein (1979, 1988) and economists such as Andre Gunder Frank (1966, 1967) consider European imperial expansion as part of a much larger history of the expansion of capitalism as a world-system, in which shifting economic cores and peripheries are mutually constituted through abiding asymmetric economic and political relationships. Others emphasize imperialism not so much as an economic but as a cultural and ideological force associated with European hegemony. In this wider and more general sense, imperialism has been related to post-Darwinian biological theories of race, theories of western industrial and technological superiority, militant nationalism, orientalism, and also modern-day environmentalism. Subject to such wide-ranging usage, imperialism is harder to define in the present context as a specific set of ideas. Rather, it is more accurately described as an all-purposive political orientation, no longer focused on the extension of the sovereignty of the European nation-states beyond their internationally recognized boundaries, but much more on the political condition of a collective present (Hardt and Negri 2000) marked by a post-European global hegemony of displaced and multilocal capitalism.

IMPORT PENETRATION

The export ratio and import penetration rate are important concepts in considering a country’s trade structure. A search of the American Economic Association’s EconLit, a leading database of economics literature, resulted in 142 articles (as of April 2006) that have been published since 1969 and use the term import penetration. The oldest of these is by James Hughes and A. P. Thirlwall (1977).

The relationship between domestic output, represented by Y, and domestic demand, represented by D, can be expressed as follows: Y = D + EX - IM, with EX representing exports, and IM, imports.

The export ratio is the percentage of domestic output that is exported—in other words, EX/Y. The import penetration rate (IP), on the other hand, is the percentage of domestic demand fulfilled by imports (OECD 2003):

\[
IP = \frac{IM}{D} = \frac{IM}{Y - EX + IM}
\]

To illustrate, if domestic television sales during a year amount to two million units, and the number of televisions imported totals 800,000, the import penetration rate would be calculated as follows:

\[
\frac{80}{200} \times 100 = 40(\%)
\]

The concept of the import penetration rate is important in relation to particular industries, as well as to the entire macroeconomy, and it has been a focus of much research. Representative studies were performed by Howard Marvel (1980) and Stephen Rhoades (1984), who analyzed the relationship between concentration and the import penetration rate for its potential as a way to integrate industrial organization and international economics, and Avinash Dixit (1989), who researched the relationship between the import penetration rate and exchange rate pass-through.

From a macroeconomic perspective, a country that produces manufactured goods with a high degree of international competitiveness will see increasing exports and decreasing imports. Under these circumstances, the export ratio will rise and the import penetration rate will fall. Conversely, a country that produces manufactured goods with a low degree of international competitiveness will see decreasing exports and increasing imports. In this case, the export ratio will fall and the import penetration will rise. It must be noted, however, that the relationship described here does not always hold. Two factors—import barriers and transaction costs—may interfere with it. If a country has established import barriers, another country’s comparatively better manufactured goods will have little impact on its imports, and its import penetration rate will not rise. Likewise, if transportation and other transaction costs are extremely high for traded goods, differences in international competitiveness may not be reflected in the import penetration rate.

At the industry level, the export ratio and import penetration rate reflect a country’s industrial structure. In the case of a developing country, for example, there is a
tendency to export a significant volume of primary goods and to import large quantities of industrial goods. As a result, developing countries often have high export ratios for primary goods and high import penetration rates for industrial goods. Industrialized countries, in contrast, export significant volumes of industrial goods and import large quantities of primary goods. Industrialized countries, therefore, often have high export ratios for industrial goods and high import penetration rates for primary goods.

It must be noted that low (high) import penetration rates do not necessarily mean that there are high (low) import barriers. In actuality, a low import penetration rate may reflect a particular set of industrial characteristics that are unfavorable for international trade (e.g., high transportation costs). Furthermore, the combination of a high export ratio and low import penetration rate may be an indicator of the high competitiveness of domestic companies. When the export ratio and import penetration rate are both high for a particular industry, it may very likely be that such factors as intra-industry trade have resulted in a high degree of internationalization.

Figure 1 shows the changes in the import penetration rates of the Group of Seven (G7) countries (Canada, France, Germany, Italy, Japan, the United Kingdom, and the United States) between 1991 and 1999. As this graph clearly indicates, import penetration rates in all of the G7 countries rose during this period. This may reflect an increasing degree of internationalization over these nine years.

IMPORT PROMOTION

Import-promotion policies are measures intended to increase the volume of a country's imports from a particular trading partner or group of trading partners. Such policies may include bilateral agreements, bureaucratic directives, import subsidies, or procedures to improve foreign exporters’ information about domestic market opportunities. Many countries have used trade policy to spur development of their own domestic industries, either by restricting competition from imports (import substitution) or by expanding exports (export promotion). Import promotion, which has the effect of increasing the foreign competition faced by domestic firms, is much less common.

Among major trading countries, import promotion has been employed to defuse political tensions arising from large bilateral trade imbalances, particularly the record trade surpluses of Japan and other East Asian countries during the 1980s. Voluntary import expansion (VIE) agreements between the United States and Japan set numerical targets for Japanese imports of specific U.S. products including semiconductors, automobiles, and auto parts. The United States later negotiated VIEs for rice and beef with South Korea, another country running a large bilateral surplus on trade with the United States.

VIEs, along with the more common voluntary export restraints (VERs), are results-oriented trading arrangements in which politically acceptable trade outcomes are negotiated bilaterally, in contrast to rules-based relationships, in which underlying economic conditions determine trade flows and trade balances given those rules. Results-oriented bilateral agreements, which were negotiated outside the General Agreement on Tariffs and Trade (GATT), failed to satisfy the GATT’s most-favored-nation (MFN) principle—that a country should not discriminate among its trading partners. By promoting imports from one specific source, VIEs allowed imports from the favored source to displace lower-cost exports from other countries (trade diversion). VERs likewise diverted trade, with higher-cost goods from other sources replacing exports from the restricted supplier. Bilateral trade commitments also weakened competition among suppliers of affected products, thus raising their profits. Moreover, because compliance with negotiated commitments required coordination of purchases or sales, VIEs facilitated collusion among affected importing firms; VERs likewise facilitated collusion among exporting firms.

More recently, advanced countries have used import-promotion policies to assist potential exporters in developing and transition economies. For example, import-promotion agencies in a number of European countries supply information about market opportunities, organize trade fairs for small and medium-sized firms in developing and transition countries, and offer technical assistance to potential exporters. These efforts complement the Generalized System of Preferences (GSP), which allows manufactured exports of lower-income countries preferential access to the markets of industrialized nations, and broader programs offering duty-free market access to most exports from the least-developed countries. In contrast to negotiated bilateral arrangements, these import-promotion efforts are a form of development assistance that is extended to a large class of countries. The aim is to improve efficiency by overcoming informational gaps that would otherwise prevent smaller firms in poor countries from penetrating export markets. Affected exporters are likely to benefit through increased sales abroad as well as higher prices for their products. However, as with VIEs, these policies discriminate among potential trading partners and thus run the risk that the imports promoted will displace lower-cost products from ineligible exporting nations.

IMPORT SUBSTITUTION

Import substitution, also referred to as import substitution industrialization (ISI), is a set of policies that addresses the developmental concerns of structurally deficient economic countries. As the name suggests, the ultimate goal of ISI is to promote a country’s economic industrialization by encouraging domestic production and discouraging imports of consumer goods.

The dependency theorists were the first to formally devise import substitution as a viable economic strategy. Inspired by Karl Marx and Friedrich Engels's writings on
imperialism, the dependency theorists characterize the international system as divided between countries of the core and those of the periphery. In contrast to the industrialized nations of the core, the peripheral countries are poor and lag behind technologically. Another trait of the countries of the periphery, according to this school of thought, is their inability to influence economic outcomes in the international realm. The asymmetry in power relations between core and peripheral countries is borne out of the unfavorable economic exchanges that developing countries have with the developed world. This theory asserts that developed nations utilize their economic superiority to influence, and often intervene in, the peripheral countries’ economic, diplomatic, and military interests.

The dependency theorists contend that developing nations are bound to experience balance of payments problems due to declining terms of trade; that is, their ability to use earnings from agricultural (or other primary) exports to pay for industrialized (and high value-added) imports from developed nations is likely to diminish (Hirschman 1971). Hence, they argue that developing countries can enhance their international strategic position by reducing, or eliminating, their trade dependence on wealthy nations if they substitute their industrialized imports for goods manufactured domestically.

Besides the theory that inspires ISI policies, past international crises have forged a consensus among developing countries for the need to promote their local industries. The Great Depression and the two world wars were devastating for developing countries, whose industrialized imports from the developed economies were drastically interrupted. The economic success of the Soviet Union during the first half of the twentieth century also inspired policy makers throughout the developing world, including proponents of capitalism, who were persuaded by the apparent efficacy of a centrally planned economy. Indeed, the political and economic elites of peripheral countries were convinced that the state had to lead the crucial task of promoting domestic industry. Policy makers believed that a well-conceived and coordinated state intervention in the economy would eventually enable peripheral countries to catch up economically to the developed nations, which had the historical advantage of being the first ones to achieve industrial development.

In a nutshell, import substitution is a government-led, tightly staged economic strategy aimed at promoting industrialization by offering a package of subsidies to its local industries (which are oftentimes government owned) and by insulating infant industries from foreign competition. Two important tasks of a successful ISI strategy are to persuade domestic consumers to buy locally produced goods and to encourage domestic producers to participate in the country’s industrialization project. ISI policy tools include:

1. High import tariffs on consumer goods
2. Low or negative tariffs on imports of machinery and intermediary inputs
3. Cheap credit (frequently at negative real interest rates) to industrial firms
4. Preferential exchange rates for industrial producers
5. Public investment in infrastructure (e.g., transportation and power) and in so-called basic industries, such as steel (Weaver 1980)

One important feature of ISI is the tendency to transfer income from agricultural exports to industrial development. Countries that adopt this economic strategy in effect penalize their agricultural sectors, even though most of these countries enjoy significant comparative advantages in agricultural production. Michael Lipton (1977) denounces this practice as “urban bias,” namely, policies that favor urban industrial producers and labor at the expense of farmers and workers in rural areas. Some of the policies that characterize urban bias are overvalued real exchange rates, which penalize the export sector; price controls on domestic sales of locally produced agricultural goods as a means to subsidize food consumption in urban centers; and heavy taxation on agricultural exports. Therefore, one could argue that import substitution results in economic autarky.

**ECONOMIC PROBLEMS ATTRIBUTED TO ISI**

Despite widespread enthusiasm in the 1940s and 1950s, levels of economic success among governments that pursued ISI policies tend to vary across regions and countries. Nevertheless, a common pattern exists among the ISI countries that achieve material domestic industrialization: They all tend to have large domestic markets. In Latin America, for example, some of the countries with relatively successful ISI experiences include Argentina, Brazil, and Mexico, the three largest countries in the continent. Scholars believe that import substitution cannot succeed as a development strategy without the support of a fairly large domestic market. Such markets are necessary to encourage local production.

Unfortunately, import substitution has left a devastating legacy in Africa, where most ISI economies have experienced stagnant or declining production in their agricultural sectors. Since 70 percent or more of the African population earns its income from agriculture, the urban bias that characterizes import substitution has resulted in a reduction in the real income of those who are among the poorest in the region (World Bank 1981).
Some of the other economic problems attributed to ISI include:

1. An increase in state bureaucracy and in administrative inefficiency, in part because of the government’s excessive intervention in the economy;
2. Increased fiscal deficits, which are primarily caused by governmental investments in heavy industry despite the lack of public resources;
3. Chronic real exchange rate misalignments resulting from the maintenance of overvalued exchange rates;
4. A shortage of foreign exchange, mostly due to the countries’ poor trade performance;
5. An increase in foreign debt because ISI economies tend to borrow heavily from international capital markets to finance their development strategies;
6. An increase in income inequality, especially between rural and urban workers; and
7. An increase in balance of payments problems due to the importation of heavy machinery by domestic industry.

Of all the problems associated with import substitution, arguably the latter is the most ironic. A reduction in trade dependency on developed nations is precisely one of the main objectives in the pursuit of ISI strategy. Since the late 1980s there has been little support for import substitution among scholars. However, the economic nationalism that motivated much of this economic strategy has not completely gone out of fashion.

IMPORTS

Imports are products or services shipped from producers in one country to users who are located in another country. While many import transactions involve a distinct buyer and seller, not all imports involve a market transaction, since some imports arise when a producer in one country ships its products to an associate or affiliate abroad.

The pattern of import demand—whether a country imports shoes, electronics, and oil, or some other bundle of goods and services, for example—is partially determined by international differences in comparative advantage. Such differences are driven by cross-country differences in the relative endowments of capital, labor, and other resources or by cross-country differences in productivity across products. Import patterns are also influenced by customer desire for variety. Since expanding product varieties generally requires firms to make fixed-cost investments in the development of new varieties as well as the construction of new production facilities, producers in different countries specialize in distinct varieties of a product, and a limited range of varieties are available from each country. Thus, when individuals prefer a particular car, chocolate, or cheese that is not produced at home, they may import their preferred variety from the country that produces their preferred variety or brand.

Multinational firms—firms whose plants, offices, and facilities are located in more than one country—play an important role in the movement of imported goods, since multinational firms’ networks of overseas affiliates both

create and support international import transactions. To demonstrate the importance of multinational firms in the mediation of trade, Table 1 shows the percentage of U.S. import value in 2003 that involved a multinational firm at the shipping or receiving end of the transaction. For example, of the $1,257 billion in goods imported into the United States in 2003, 65 percent of the transactions involved multinational firms. Similarly, noting that U.S. exports become another country's imports, 78 percent of the $725 billion of U.S. goods exported in 2003 involved multinational firms. In each of these examples, there were two potential avenues for engagement by multinational firms: the first avenue involved American-owned multinational firms, while the second involved foreign-owned affiliates operating in the United States.

The networks and presence of multinational firms were also notable in the conduct of services trade. Data from the U.S. Bureau of Economic Analysis show that other countries imported $769 billion of services from the United States in 2003, 62 percent of which involved the participation of U.S. service affiliates located overseas (Nephew, Koncz, Borga, and Mann 2005). Similarly, 63 percent of U.S. service imports in 2003 were conducted via the U.S.-based affiliates of foreign-owned firms (Nephew, Koncz, Borga, and Mann 2005).

While countries differ in the percentage of their imports handled by multinational firms, a portion of each country's trade is likely to involve multinational firms. At the most basic level, firms often enter into operation as a multinational when they set up an overseas affiliate dedicated to the distribution of their products in foreign countries. Over time, the multinational firm's presence in the foreign country may allow it to expand its foreign sales, and consequently the imports of the foreign country, since affiliate operations help firms to learn which of their products best match local tastes. If the local demand is sufficiently different and the foreign market is sufficiently large, the foreign affiliate may enable the multinational firm to tailor its products or services to the specific nature of foreign customer demands.

While the international networks of multinational firms often stimulate import flows, the operation of foreign affiliates may reduce import volumes. This outcome is especially likely when the multinational firm uses the output of its foreign subsidiary to serve its foreign customers, rather than having the foreign customers import the firm's product. This type of substitution is especially likely when import tariffs are high, or international transportation costs are large, since the multinational firm maximizes its profits by producing in a foreign subsidiary, rather than engaging in international trade in its products. In contrast, when the cost of creating a new plant in a foreign location is large, the profit-maximizing multinational will be more inclined to produce in a more limited number of locations, or even a single location, thus requiring foreign customers to import their products. Since the cost of creating a new production facility does not vary dramatically across countries, this suggests that the displacement of imports by subsidiary production will be greatest for countries with large markets, where the variable cost savings due to lower transportation costs and tariffs more than compensate for the added fixed costs of building a new production plant overseas.

Production by a multinational firm's overseas affiliates stimulates demand for imported intermediate inputs that are used in the foreign affiliate's production. In many instances, these transactions give rise to intrafirm imports, where the multinational firm is both the shipper and recipient in the import transaction. For example, the production of cars in Toyota's U.S. assembly plants generates intrafirm imports when Toyota's U.S. assembly plants import engines from Toyota-owned production facilities in Japan. As Table 1 shows, 38 percent of U.S. imports and 32 percent of foreign imports of U.S. goods represented intrafirm transactions, which placed the same multinational firm as the shipper and receiver of the imported goods.

More broadly, increasing vertical specialization in international trade allows production to be decomposed across countries, as each country contributes to some elements of the production process. The international trade incentives for engaging in vertical specialization are identical to the motives driving the demand for imports of final products. However, in vertical production relationships, comparative advantage determines which stages of production are conducted in each country along the production process. For a broad range of countries, David Hummels, Jun Ishii, and Kei-Mu Yi (2001) estimate that vertical specialization, involving the trade of both affiliated and unaffiliated firms, represented 20 percent of all trade by 1990, and that the growth of vertical specialization was responsible for 30 percent of the growth in trade between 1970 and 1990. As tariff and transportation costs continue to decline, and technologies for international communication and coordination improve, vertical specialization imports should grow further yet.

IMPRISONMENT

Imprisonment is a political act. Until early-nineteenth-century reforms, lockups most often confined people awaiting trial. Earlier political elites, kings and queens for example, locked away their opposition, critics, or competitors in dungeons or, in the case of enemies of the English Crown, the Tower of London. Common criminals were often executed, were banished, or received corporal punishment. The concept of the European and North American prison as a primary form of punishment was a reform advocated by individuals such as the Italian jurist Cesare Beccaria (1738–1794) and the American reformer Jeremy Bentham. Early American prisons in Pennsylvania and New York were thought to provide a more reasonable alternative than previous practices, which reformers believed were too often cruel and capricious.

Imprisoning offenders provides a rational means of punishment because the length of incarceration can be tied to the severity of the offense or offenses. Which crimes people will be imprisoned for and for how long are decisions that are made in political arenas. In the late twentieth century the Soviet Union, South Africa, and the United States were the nations with the largest portions of their populations in custody. With the collapse of the Soviet Union and the subsequent release of political prisoners, the demise of apartheid and the consequent liberation of democracy advocates and freedom fighters, the United States moved into the lead. Since then, the war on drugs and other “get tough” practices have led to a quadrupling of the number of American inmates. Officials of both major political parties have supported such practices because they want to run for reelection on “get tough on crime” platforms, and they fear being painted as “soft on crime” by the opposition. Thus, the consequences for criminal acts, including length of incarceration, are essentially outcomes of the political process, involving politicians, public interest groups, and advocates.

Decisions have been made against a backdrop of two competing visions of the role of prisons. Is their primary purpose punishment or rehabilitation? Estimates of recidivism rates frequently have surpassed two-thirds when corrections officials were concerned about rehabilitation and when punishment was stressed. With such limited success with either philosophy, legislatures often “reform” and alter sentencing and imprisonment policies based on what will garner votes, rather than a rational penology.

PRISON SYSTEMS IN AMERICA AND ABROAD

Evidence of the political and economic underpinnings of imprisonment in the United States can be seen in the history of race and American incarceration. Prior to the Civil War very few blacks were ever confined in prison. Most African Americans lived in southern states and most were slaves. Freedmen found guilty of crimes were frequently re-enslaved. Bondsmen who were thought to violate the law were more likely to be punished by their owners and not imprisoned (even though white offenders might be locked up), because to do so deprived southern elites of workers. After the demise of Reconstruction in the late 1870s the prisoner lease system was instituted in the South. This system of “renting” convicts (which included more blacks, now that they were not enslaved) to work on plantations, in mines, on railroads, and in other laborious or dangerous industries provided cheap labor, but it also buttressed the Jim Crow racial caste structure that emerged. Although Jim Crow laws no longer exist in the United States, an argument among researchers remains: What role does race play in the rates of imprisonment, and what percentage of minority imprisonment can be justly accounted for by minorities’ higher levels of involvement in crime?
In societies with heterogeneous populations race and ethnicity are important determinants of imprisonment. Michael Tonry’s *Ethnicity, Crime, and Immigration* (1997) presents studies of race, immigration, crime, and criminal justice practices in Europe, Australia, Canada, and the United States. The countries included, with the exception of Australia, do not have the oppressive domestic racial history of the United States or its level of racial disparity in imprisonment. In Australia the treatment of Aboriginal people has been racist. Nevertheless, studies included by Tonry document important shifts in criminal justice practices as the number of people defined as “outsiders” grows. Within the United States, the debate continues to be not about whether racial unfairness results in disproportionate confinement of African Americans and Latinos, but how much of observed racial disparities in imprisonment are due to unwarranted, discriminating treatment. As European nations develop more diverse populations it is likely that they too will have growing disparity in imprisonment and debates that parallel those in the United States. Europeans will have to consider what portion of racial and ethnic imprisonment disparities result from higher criminal involvement among “others”—probably in part a result of their political, economic, and social disadvantages within the society—and what portion are consequences of the politics of imprisonment.

Nations still use prisons to stifle political dissent: Amnesty International regularly publishes lists of nations that use prisons to violate human rights. Litigation resulting from U.S. policies that lock up “criminal combatants” in the “war on terror,” with neither constitutionally guaranteed due process nor supposed Geneva Convention protections, is likely to continue for decades in either American or international courts.

**EFFECTS ON ECONOMY AND COMMUNITY**

There are two additional important aspects of imprisonment: its differential economic effects and its effects on communities. In 2004 Bruce Western and his colleagues showed that racial and class inequalities have been maintained, in part, by U.S. imprisonment patterns. For example, their research shows that the reduced number of unemployed African Americans is a consequence of the increased number of blacks who are held in confinement rather than as a result of any improving economic fortune; they have simply been removed from both the labor market and the unemployment roles. When eventually released, they will then have considerably poorer employment prospects than before their incarceration.

The massive increase in U.S. imprisonment has also been detrimental to communities. In 1998 Dina Rose and Todd Clear demonstrated that when large numbers of people are forcibly removed from communities by incarceration, the social structure is destabilized, opening the door for social problems, including increased crime. Also, released inmates tend to return to the same neighborhoods they lived in prior to imprisonment. They bring back their increased social and economic disadvantage and social stigma. When the released are concentrated in already disadvantaged neighborhoods, they further destabilize those communities.

Few argue that imprisonment is not a better form of punishment than the arbitrary and frequently cruel practices that it replaced, and even fewer will suggest that incarceration is not a necessary practice in complex societies. Too often, however, there is little recognition of the political nature of imprisonment and the social and economic consequences of incarceration.

**IN VIVO TRANSFERS**

In vivo transfers are gifts living parents give to their adult children. In other words, in vivo transfers can be likened to bequests, the main distinction being that with an in vivo transfer, the transfer occurs between two living persons. According to the life-cycle permanent income hypothesis (Kotlikoff 2001), an individual saves and borrows in order to smooth consumption in the face of income fluctuations. Like bequests, in vivo transfers affect the utility and budget constraints of individuals who are concerned about the future welfare or happiness of their children. This theory of consumption further predicts that changes in tax structure may influence consumption patterns over time.

Any change in fiscal policy, uncertainty, costs, preferences, and the like provides an incentive for individuals
concerned with the future happiness of their children to change their consumption, saving, and wealth-accumulation behavior and provide in vivo transfers. An obvious incentive provided by a tax on transfers of wealth at death is for taxpayers to arrange to transfer wealth before dying by making gifts to their heirs. As such, the gift tax is the government’s response to such efforts to avoid inheritance taxes. In short, according to the life-cycle permanent-income hypothesis, tax policy may have important implications for in vivo transfers and bequests.

Joseph Altonji, Fumio Hayashi, and Laurence Kotlikoff (1997) test whether in vivo transfers are motivated by altruistic concern by individuals for their children. They find that parents increase their transfer by a few cents for each extra dollar of current or permanent income they have, which in itself is consistent with altruism. Interestingly, they also find that parents reduce their transfer for every increase in their children’s income. Using French data, Luc Arrondel and Anne Laferrière (2001) also report evidence that transfer behavior is responsive to changes in the fiscal system. In contrast to Altonji, Hayashi, and Kotlikoff, Arrondel and Laferrière find no support for altruism. In their view, no legal or fiscal system is so strong and so detailed as to determine family behavior, but some individuals seem to use the tax system to optimize their transfers. They find strong behavioral responses to tax incentives. The empirical tests do not validate a single model of intergenerational transfers. They conclude that altruism seems to be involved at the time in the life-cycle when children are young adults, but the gifts are of comparatively small amounts. Altruism is harder to detect from the study of total in vivo gifts.

Ernesto Villanueva (2005) found some evidence that public help may displace in vivo transfers. Tentative estimates suggest that in West Germany, an extra dollar of public help displaces between 8 and 12 cents of parental transfers. Those results are somewhat smaller than corresponding estimates from the United States reported by Robert Schoeni (2000). That is, following a cut in unemployment benefits, individuals who have access to private help are less likely to see their standard of living affected by the change. Comparing in vivo transfers in size and incidence between ethnic groups, using data from the mid- to late-1980s, Mark Wilhelm (2001) found that annually whites had a higher likelihood of receiving a transfer and that it was on average a larger amount for whites than non-whites. The average amount received was $2,824 for whites and $805 for non-whites. The average incidence of receipt was 20 percent for whites and 17.8 percent for non-whites.

Using U.S. data, David Joulfaian and Kathleen McGarry (2004) examine the responsiveness of in vivo transfers to changes in tax laws. They find that many wealthy individuals do not take full advantage of the ability to make in vivo transfers free of estate and gift taxes, as long as the gift is less than approximately $40,000 per year, and those who do make in vivo transfers do so only on a one-off basis. Further, they find that there are sizable shifts in the timing of giving in response to tax changes, but the wealthy do not make sizable in vivo transfers over time.

In summary, there is considerable evidence that taxes and specifically estate and gift taxes appear to influence decisions to make in vivo transfers.

**INADA CONDITIONS**

Economists usually posit that production can be represented by a mathematical function that relates output to input factors. One assumes that aggregate production ($Y$) depends on the two input factors capital ($K$) and labor ($L$). Formally, the process relating output to the inputs is described by the function $F(K, L) = Y$, where
more input raises output. The function \( F(\cdot) \) is assumed to be linearly homogenous, so that production can be written as \( Y = L \cdot F(K/L, 1) \), stating that raising capital and labor by a certain amount leads to a proportional rise of production. Given this property, production per labor input, \( y = Y/L \), can be written as \( y = f(k) \), with \( k = K/L \) capital per labor. The function \( f(\cdot) \) is increasing in \( k \) continuously, meaning that jumps are excluded, and it is continuously differentiable, implying that the derivative of the function exists and is itself a continuous function.

In addition, \( f(k) \) satisfies the following conditions, called the Inada conditions, which are ideal assumptions about its shape:

- The value of the function at 0 is zero, \( f(0) = 0 \)
- The function is strictly increasing in \( k \), \( f'(k) > 0 \), with \( ' \) denoting the derivative
- The derivative of the function is decreasing so that the function is strictly concave, \( f''(k) < 0 \)
- The limit of the derivative approaches plus infinity when \( k \) goes to zero, \( \lim_{k \to 0} f'(k) = \infty \)
- The limit of the derivative approaches zero when \( k \) goes to infinity, \( \lim_{k \to \infty} f'(k) = 0 \), for \( k \to \infty \)

These conditions were named after the Japanese economist Ken-Ichi Inada (1925–2002), who wrote a number of important papers on welfare economics, economic growth, and international trade.

The Inada conditions guarantee that a unique steady state in the neoclassical growth model exists and is stable. The Inada conditions are purely technical assumptions and are hardly relevant for empirical economics. The neoclassical growth model is described by the differential equation \( dk(\cdot)/dt = s \cdot f(k(\cdot)) - (n + \delta) \cdot k(\cdot) \), where \( s \) is the constant savings rate, \( n \) is the growth rate of labor, \( \delta \) is the depreciation rate of capital, and \( t \) denotes time. This equation states that the change in capital per labor equals savings per labor in the economy, which are equal to investment, minus that part of capital per labor that is used up due to depreciation and due to the growth of the labor force. A steady state is defined as a situation with \( dk(\cdot)/dt = 0 \) so that capital per labor is constant over time. Total investment, \( I(\cdot) \), in the economy then equals \( (n + \delta) \cdot K(\cdot) \), so that the total capital stock grows at the same rate as labor. Given the Inada conditions, there exists a unique value \( \hat{k} > 0 \) solving \( dk(\cdot)/dt = 0 \), because \( s \cdot f(\cdot) \) is larger than \( (n + \delta) \cdot k \) for values of \( k < \hat{k} \), and it is smaller for values of \( k > \hat{k} \). Figure 1 illustrates the situation graphically. In addition, \( k < \hat{k} \) is stable because for \( k < \hat{k} \) capital per labor rises, \( dk(\cdot)/dt > 0 \), and for \( k > \hat{k} \) capital declines, \( dk(\cdot)/dt < 0 \).

**Incarceration, Japanese American**

From 1885 to 1924 approximately 200,000 Japanese immigrated to Hawai‘i, and 180,000 Japanese immigrated to the mainland United States. This first generation of immigrants (Issei) built a vibrant community, raising families, starting churches, and forming social and business organizations. Their success met with prejudice and an anti-Japanese movement. Discriminatory laws prevented Issei from becoming naturalized U.S. citizens. They were barred from owning land, marrying whites, and sending their children to schools attended by whites. In 1924 Congress passed the Immigration Act, which barred any further immigration from Japan. The second generation (Nisei) also faced discrimination. Even though they were born in the United States, spoke English like other Americans, and often did well in school, these U.S. citizens of Japanese ancestry faced discrimination in employ-
Incarceration, Japanese American

ARREST OF COMMUNITY LEADERS
On December 7, 1941, Japan attacked U.S. military bases in Pearl Harbor, Hawaii. More than 3,500 American servicemen and civilians were killed or wounded. In the hours following the attack, the FBI arrested over 1,200 Japanese immigrant men: businessmen, Buddhist priests, Japanese language teachers, and other community leaders.

More than 5,500 Issei men were eventually picked up and held as potential threats to national security. Most of these men were taken first to Immigration and Naturalization Service (INS) detention stations and then to Department of Justice (DOJ) internment camps to undergo hearings. Officials, these internment cases were given individual legal review, but in practice the majority of Issei were imprisoned without evidence that they posed any threat to national security. Internees were not allowed legal representation. Approximately 1,700 were "released" to War Relocation Authority (WRA) concentration camps after these hearings, but most were transferred to U.S. Army internment camps.

MASS REMOVAL OF U.S. CITIZENS
On February 19, 1942, President Franklin D. Roosevelt (1882–1945) signed Executive Order 9066, which authorized military commanders to designate military areas from which any person could be excluded. Congress supported the executive order by authorizing a prison term and fine for a civilian convicted of violating the military order. General John L. DeWitt (1880–1962), Western Defense Command, then issued over one hundred military orders that only applied to civilians of Japanese ancestry living in the West Coast states. Thus the president and Congress authorized the removal and incarceration of over 110,000 people based solely on race with¬

Ironically, over 150,000 people of Japanese ancestry in Hawaii were not removed or incarcerated. General Delos Emmons (1888–1965), who became commanding general in Hawaii shortly after the bombing of Pearl Harbor, treated the Issei and Nisei as loyal to the United States. Although there were many false stories of Japanese American spies, General Emmons repeatedly rejected anti-Japanese pleas for mass removal of Japanese ancestry from Hawaii. He knew there was no evidence of Japanese American espionage or sabotage. In fact during World War II (1939–1945) no Japanese American in the United States, Hawaii, or Alaska—citizen or immigrant—was ever convicted of espionage or sabotage.

DISPERAL TO DETENTION SITES THROUGHOUT THE UNITED STATES
The general public, through books, movies, and school lessons, is most familiar with the ten WRA concentration camps, such as the Manzanar "relocation center" near Independence, California. The full extent of the imprisonment, however, included approximately sixty other government facilities: temporary "assembly centers," immigration detention stations, federal prisons, and internment camps. Italian and German immigrants, Alaskan natives, Japanese Latin Americans, and Japanese Hawaiians were also sent to live at these sites.

Which detention facility a person entered depended on several factors, including citizenship status, perceived level of threat, geography, degree of cooperation or protest, and sheer chance. For the most part the DOJ and U.S. Army camps interned first-generation men who were arrested by the FBI, while the WRA concentration camps incarcerated both U.S. citizens and immigrants affected by the exclusion order.

SOME LEAVE CAMPS: "DISLOYALS" TRANSFERRED TO TULE LAKE
As early as April 1942, even before inmates were transferred from the temporary "assembly centers" to concentration camps, the WRA recognized that Japanese Americans eventually would have to reenter society. Thus the WRA enacted a policy of granting short-term or indefinite leave for college or work to Japanese Americans who were U.S. citizens and who could find sponsors. Additionally, thousands of Nisei men enlisted in the military and served in combat.

To help administer the military draft and work-release program, the U.S. Army and the WRA produced "loyalty questionnaires" for all WRA inmates seventeen years of age and older. Two questions caused confusion and controversy for inmates. They were asked if they were willing to serve in the armed forces and to forswear loyalty to Japan. Answering "yes" left the Issei stateless, as they could not be U.S. citizens and the wording falsely assumed the American-born Nisei were loyal to Japan. Despite serious problems with the meaning and purpose of the questions, government officials and others considered those who answered "no" to these two questions to be "disloyal" to the United States, and they were transferred to the Tule Lake concentration camp in northern California, which was designated a segregation camp. "Yes" answers to these questions qualified inmates for service in the U.S. Army, and some became eligible for release and resettlement in areas outside of the West Coast exclusion zones.
GOVERNMENT ENDS WEST COAST EXCLUSION

In December 1944 the U.S. Supreme Court ruled in the case brought by Mitsuye Endo, a Nisei contesting her incarceration, that a loyal U.S. citizen could not be held in a WRA concentration camp against his or her will. While the case was being heard, federal officials recognized that the continuing incarceration was not legally defensible and began preparations to close the concentration camps. In addition the exclusion orders were rescinded, and persons of Japanese ancestry were allowed to return to the West Coast. On March 20, 1945, the last WRA concentration camp, Tule Lake, was closed. The DOJ internment camps remained open longer. The last internment camp to close was the DOJ camp in Crystal City, Texas, in January 1948.

Upon release the majority of those who had been incarcerated were given $25 and one-way transportation. Many of the freed Japanese Americans returned to discover that their homes and farms had been vandalized and their belongings stolen. Even Nisei military veterans returning home in their uniforms from combat duty endured racist insults. Starting over was especially hard for the Issei, who were entering their senior years with little to show for a lifetime of work.

ADMISSION OF WRONGDOING: APOLOGY FROM THE GOVERNMENT

In the late 1960s community activists started a movement to petition the government to look into potential wrongdoings. Classified information was uncovered that showed that the exclusion order and incarceration were based on racism and falsehoods. In February 1980 Congress passed an act forming the Commission on Wartime Relocation and Internment of Civilians (CWRIC). This commission conducted hearings in 9 cities, heard testimonies from over 750 witnesses, and examined over 10,000 documents. In 1983 the CWRIC issued its report, which concluded that military necessity was not the cause of the mass imprisonment. Rather, “the broad historical causes which shaped these decisions were race prejudice, war hysteria and a failure of political leadership” (Commission on Wartime Relocation and Internment of Civilians 1983, p. 18).

Acting upon the recommendations of the commission, Congress passed the Civil Liberties Act of 1988, and President Ronald Reagan (1911–2004) signed it into law. This law required payment and apology to survivors of the incarceration caused by Executive Order 9066. Two years later President George H. W. Bush presented the first apologies along with payments of $20,000 to each of the oldest survivors.

INCAS

The Inca Empire was the last and greatest of several civilizations that existed in South America prior to the arrival of Europeans in the sixteenth century. The Incas began as one of many small, warring chiefdoms in central Peru. At its height in 1532 CE, the empire stretched from central Ecuador to south central Chile, and encompassed high altitude grasslands, coastal deserts, and tropical forests.

The dates for the Inca Empire are under debate. From study of Spanish documents, the late John Rowe, professor of anthropology at University of California, Berkeley, determined that the Incas began their expansion out of the region of Cuzco, their capital, around 1438 CE. Although archaeological work has suggested that the expansion actually began before that, the fact remains that the Incas created their empire in a remarkably short time, less than two centuries.

The success of the Incas was based on two main factors, a large and well-disciplined army and an effective administrative system. The Inca army was made up of a core of seasoned troops augmented by a large number of part-time soldiers, all led by a group of outstanding generals. The Inca army was successful also because of an effective infrastructure. The Incas built or expanded earlier road systems to make up more than 40,000 kilometers of roads. At regular intervals were major centers where provisions were collected from conquered people.

The success of the Incas was based on two main factors, a large and well-disciplined army and an effective administrative system. The Inca army was made up of a core of seasoned troops augmented by a large number of part-time soldiers, all led by a group of outstanding generals. The Inca army was successful also because of an effective infrastructure. The Incas built or expanded earlier road systems to make up more than 40,000 kilometers of roads. At regular intervals were major centers where provisions were collected from conquered people.
The Incas required labor, but little else, from their subjects. A conquered group had their land divided into three parts: one part each for the use of the Inca state and Inca religion, the third part remaining for the people’s use. One labor obligation was working the Incas’ parts first. Every household was also required to provide labor service, called mit’a, for a certain period each year. This labor might entail warfare, craft production, carrying messages, or building activities. The Incas provided all the food and materials for the mit’a labor. They also moved communities all over the empire to maximize food production and for political reasons. In this way, the Incas created an agricultural base and vast labor pool for both expanding their empire and creating the material and luxury goods that were needed to run it.

The Incas never developed a writing system, but used a knotted cord device called a quipu to keep track of goods and labor. Specially trained individuals, called quipucamayocs, were in charge of maintaining these records. The Inca administrative system was a hierarchical one, and was based on a decimal system of counting. The empire was ruled by the king, and consisted of four unequal parts, called suyus, that originated at Cuzco. Each suyu was made up of provinces, which were ideally divided into two or three sayas, units of 10,000 families. The sayas might correspond to a conquered ethnic group, or be a combination of smaller ones. Suyus, provinces, and sayas all had separate leaders. Within each saya, households were organized into a series of progressively smaller administrative units, led by local curacas, or leaders. There were curacas in charge of 5,000, 1,000, 500, 100, 50, and 10 families. Their jobs were to organize labor and lead their units’ troops in battle. They were rewarded with gifts for jobs well done, and punished for doing poorly. Most of the curacas were local leaders who were incorporated into the lower levels of the social hierarchy. At the top of the hierarchy were the Inca nobility, those who could claim ancestry from any of the original kings, and allied ethnicities, called “Inca-by-privilege,” who were granted Inca status. These two groups filled the highest administrative posts in the empire.

As with many ancient civilizations, Inca politics were intimately related to their religion. The Incas worshipped a host of deities of the earth and sky. In addition, the Incas revered a line of divine kings and held sacred any place that was considered imbued with supernatural power (huacas). Both the Incas and their subjects lived in fear of the displeasure of gods and huacas, and so carried out many different rituals. Although most of these involved only offerings of food or llamas, extremely important events, such as the accession of a new ruler, or a major calamity such as an earthquake, could require human sacrifice. Some of the most important Inca gods required human sacrifices as well. These sacrifices were always physically perfect children, from all over the empire. The remains of such sacrifices have been found on many of the highest peaks in the Andes.

Despite controlling a population estimated to be more than 10 million, the Inca Empire fell to a group of about 170 Spaniards led by Francisco Pizarro (c. 1475–1541). This conquest was achieved as a result of three things: a civil war between two rivals to the throne, European diseases that were introduced from Mexico, and the quick capture of the last Inca king. The latter event allowed the Spaniards to rule through the king for several months before they executed him and marched to Cuzco. A rebellion by the Incas four years later nearly succeeded, but was finally suppressed. The Spaniards introduced many new institutions, foods, and Catholicism to Andean people, yet much of the indigenous way of life still exists in regions remote from major cities.

INCOME

Income is often defined as the amount of money received during a given period of time by a person, household, or other economic unit in return for services provided or goods sold. Although this is certainly a serviceable definition, working economists need a more precise one. Many economists use a comprehensive definition of income attributed to Robert Haig and Henry Simons, that income is equal to a person’s (household’s) consumption plus the increase in his or her net worth (Haig 1921, p. 7; Simons 1938, p. 50). The two definitions differ in several respects; most notably, the informal definition refers to money received, whereas the Haig and Simons concept refers to changes in net worth.

There are important distinctions between money received, as in the informal definition of income, and changes in net worth, as in the Haig and Simons definition. For example, person A may give person B a dozen eggs for performing a service, and suppose person B uses the eggs to make breakfast. Because no money has changed hands in this example, there is no income according to the informal definition of income. In terms of Haig and Simons’s definition, however, person B’s income has changed his consumption; therefore, his income has increased by the value of the eggs. In other words, barter income is included in Haig and Simons’s income. To take another example, suppose a person buys a stock for $100 and its value increases to $150; unless he sells the stock, no money is received and his income from this asset is zero ($0.00). In terms of Haig and Simons’s income, however, his or her net worth has increased by $50, and thus there is income of $50 though no money has changed hands. In other words, accrued capital gains are included in Haig and Simons’s income.

It is useful for analytical purposes to distinguish between sources of income. Thus, economists, journalists, and policy makers often talk about wage income, dividends and interest income, transfer payments, and so on. Labor income is the income generated from working for a set wage, including tips and fringe benefits. Financial income is the income obtained from financial markets, which includes accrued capital gains, interest income, dividends, and retained earnings. Retirement income refers to pensions and retirement transfers. Government income refers to government transfers such as social insurance payments. Other sources of income include bequests, prizes and awards, and alimony payments received.

EMPirical SIGNificance

Defining income is important to the analysis of public policy. Using a measure that is not comprehensive could alter the outcome of the policy, and as such may result in poor decision making. For example, if a tax administration such as the U.S. Internal Revenue Service taxes only wage income at a single rate, then the burden of such a tax would take a higher proportion of the total income of low-income households than high-income households, because low-income households obtain a greater share of their income from wages than do high-income households. Another area of research is in the distribution of income and income inequality.

Table 1 shows the distribution of income by source for a variety of countries. The similarities in the shares of income by source among these countries are noteworthy.

Although there appears to be considerable variation in income from employment, which varies from a low of 46.86 percent in France to a high of 75.61 percent in India, income from employment and taxes and social security contributions (payroll taxes) shows much less variation, with the smallest share being 65.64 in Mexico and the highest share being 82.25 percent in Japan. Many economists believe that tax policy may explain the relative shares of gross income from benefits. Because benefits such as contributions to retirement accounts and health insurance are generally not taxable, one would expect that people living in high-tax countries such as France would prefer to receive income in the form of untaxable benefits rather than taxable sources such as wages; in contrast, in low-tax countries such as India, people would prefer to receive income as wages. This pattern is borne out in the table.

**INCOME DISTRIBUTION**

*Income distribution* captures the proportion of total income accruing to different individuals that accounts for the total income distributed among them during a certain time period. If the unit of analysis is the country, the income distribution for a certain year would show how much of the country’s yearly income went to each person. It may be of interest to capture the country’s distribution of income within and across groups of individuals as well. Groups can be formed according to many criteria, depending on the issue under analysis. Criteria can include geographic (cities or states), gender, social, and ethnic considerations, to name a few. When groups of individuals are considered, it is typically of interest to distinguish between the income distribution within and across groups. For example, how much of a country’s income goes to the urban and to the rural population corresponds to the across-group distribution of income. How much went to each person living in rural areas and how much went to each person living in urban areas is a measure of the distribution of income within groups.

Income distribution can be represented in different ways. It can be represented by an (income) density function, \( f(y) \), where \( y \) stands for income; \( f(y) dy \) gives the number of individuals earning income in the \([y, y + dy]\) interval. Integrating the income-density function to infinity yields the total population, \( N \), while integrating \( yf(y) \) gives total income, \( Y \). Mean income, \( \mu \), is given by \( Y/N \).

A plot of the income-density function would be the most comprehensive way of representing income distribution, but this is rarely possible in practice if the unit of analysis is a country. Histograms may provide an approximation, but these representations are not usually used when analyzing the dispersion in the distribution of income. The most widely used graphic representation of income distribution—while by no means the only one possible—is the Lorenz curve. To construct a Lorenz curve, individuals are first ranked by income in ascendant order: \( y_i \leq y_{i+1}, \ i = 1, \ldots, N \). Then, the cumulative income up to rank \( j \) is computed: \( s_j = y_1 + y_2 + \ldots + y_j, j = 1, \ldots, N \). The Lorenz curve corresponds to the plot of \((j/N, s_j/Y)\), \( j = 1, \ldots, N \). That is, it shows on the horizontal axis the cumulative population share (from 0 to 1) and on the vertical axis the corresponding income share (also from 0 to 1). It enables the determination of the share of income going to each quartile, quintile, decile, or centile—or any other breakdown of the population.

The Lorenz curve gives a visually compelling idea of the extent of inequality in the distribution of income. The line of perfect equality corresponds to the 45-degree line that goes from the origin to (1,1). That is, the poorest 10 percent of the population have 10 percent of income, then the poorest 20 percent have 20 percent of income, and so forth. The Lorenz curve lies always on or below the line of perfect equality, with “perfect inequality” (all income going to the richest individual) corresponding to the line that makes the lower and right-hand side of the square that encompasses the line of perfect inequality. That is, the shares of income going to all the shares of the population are zero, and 100 percent of income goes to the single individual at the top. Thus, the closer the Lorenz curve is to the line of perfect equality, the more equal the distribution of income; the farther it is, the higher the level of inequality.
Thus, intuitively, the area that lies between the line of perfect equality and the Lorenz curve provides an indication of the extent of inequality. If this area is very small, the Lorenz curve is very close to the area of perfect equality, and inequality is low. If this area is large, then the Lorenz curve is further away from the line of perfect equality, and inequality is high. The ratio of this area to the area of the triangle limited by the lines of perfect equality and perfect inequality is a number that falls always between zero (when the Lorenz curve coincides with the line of perfect equality) and one (when the Lorenz curve coincides with the line of perfect inequality and the area under the Lorenz curve is exactly the same as the area of the triangle). This number is the Gini coefficient, one of the most widely used measures of inequality—and one of the many possible summary measures of income distribution, whereby distribution is summarized by a single number.

While intuitively appealing, the Gini coefficient has a major drawback. As noted, in studies of inequality there is often an interest in grouping individuals and determining the shares of inequality that correspond to asymmetries in the distribution of income across and within groups. It is possible to decompose the Gini coefficient into within-group and between-group components, but this decomposition is not “perfect,” in the sense that the components do not add up to total inequality—a third term, a residual, is typically required to be added to the other two terms to get to total inequality. The only summary measures of inequality that are perfectly decomposable correspond to a class known as entropy-based measures of inequality, which were pioneered by the Dutch econometrician Henri Theil (1924–2000). He drew inspiration from the entropy-based analysis of information, and thus the name of this class of measures.

The most widely used entropy-based measure of inequality is the Theil index. It is bound between zero and the natural logarithm of the size of the population (and not by one, like the Gini coefficient). The Theil index is the weighted sum of the natural logarithm of the ratio of the income shares to the population shares, where the weights are income shares. When applied to measure inequality across individuals, the “population share” is merely $1/N$, so the Theil index is the weighted sum of the natural logarithm of the ratio of each individual’s income, $y_j/Y$, to $1/N$, where the weights are $y_j/Y$. When individuals are grouped, the between-group component of the Theil index is the weighted sum of the natural logarithm of the ratio of each group’s income, $Y_j/Y$, to that group’s population share, $n_j/N$, where the weights are $Y_j/Y(n_j$ and $Y$ are, respectively, the group’s population and total income). The within-group component of total inequality is given by the weighted sum of the within-group Theil index for each group, where the weights are the income shares, $Y_j/Y$. Total inequality measured using the Theil index is the sum of the between-group and within-group components.

**Income Maintenance Experiments**

The income maintenance experiments in the United States and Canada were tests of a welfare program known as a negative income tax, which was designed to assist families in need while preserving their incentives to work. The negative income tax is the most important proposal in the history of welfare reform and has been a major object of study in the social sciences.

**Origin of the Experiments**

The idea of the negative income tax is generally associated with the Nobel laureate, conservative economist Milton Friedman (1962, chap. 12), although liberal economists Robert J. Lampman (1920–1997) and James Tobin (1918–2002) were also early developers. Friedman’s proposal had both liberal and conservative elements. On the liberal side, he proposed that all families with low incomes receive an unrestricted grant from the government, leading to what some others termed a guaranteed annual income. However, Friedman noted that such a grant threatens to reduce work incentives by providing income support to families even if they are not employed. To
counter that disincentive, Friedman proposed that families be given a financial incentive to work by means of a “tax rate” that would result in higher income if they worked. For example, if the tax rate were 50 percent, a nonworking family with a monthly grant of $500 who went to work and earned $100 would experience a grant reduction of $50 (50 percent of earnings) to $450. The family’s total income would rise to $550, the sum of $100 of earnings and a grant of $450, providing the desired financial incentive. The lower the tax rate, the smaller the benefit reduction that would occur and hence the greater the work incentives.

In 1967 the federal government decided to conduct a social experiment to determine whether a guaranteed, unrestricted grant for nonworkers would induce working families to quit work and whether a low tax rate would counter that disincentive (Greenberg et al. 2003). To test the negative income tax, the government proposed to select a group of poor families, to randomly assign them to an “experimental” group and a “control” group, to give the experimental group the negative income tax, and then to later observe how many families in each group were working. The difference in the work levels of the two groups would be taken to be the effect of the negative income tax.

Four experiments were designed and implemented in the United States and one in Canada. They were located in New Jersey and Pennsylvania; South Carolina and Iowa; Gary, Indiana; Seattle, Washington, and Denver, Colorado; and in Manitoba, Canada (Greenberg and Shroder 2004). The first began in 1968 and the last ended in 1979. Most were designed as described previously, but with one variation: different families in the experimental groups were given different guaranteed grant amounts and different tax rates, allowing a test of the effect of the levels of the guaranteed income amount and the tax rate on work effort.

RESULTS OF THE EXPERIMENTS

The first question was whether offering families a guaranteed income if they did not work would reduce work effort. The answer from all the experiments was an unequivocal “Yes.” The work levels of experimental families were almost always less than those of control families (Burtless 1986; Greenberg et al. 2003; Greenberg and Shroder 2004; SRI International 1983). For example, in the Seattle-Denver experiment, married men in the experimental group were five percentage points less likely to work during the year than those in the control group; the corresponding figures for married women and for single mothers were eleven percentage points and seven percentage points, respectively. Further, the comparisons of work levels across families with different experimental plans revealed that families who were offered more generous grant amounts did, in fact, work less.

The second question was whether Friedman’s idea of giving families a financial incentive to work with a reasonably low tax rate countered this disincentive. The answer to this question was much more ambiguous. Overall, the data from the experiments showed a mixed pattern of effects of this kind (e.g., SRI International 1983, Table 3.9). Why a stronger work response to financial incentives was not found generated a great deal of research over the subsequent years, with some arguing that statistical flaws in the experiments’ design led to this result. But the leading explanation is that a reduction in the tax rate expands the generosity of the program, relative to the existing welfare program, and tends to bring new families onto welfare who had not received benefits previously. The work reductions of these families partially or wholly offset the positive work effects for those families initially on welfare.

The researchers conducting the experiments also gathered data on other aspects of behavior. For example, families in the experimental group had slightly greater expenditures on housing and increases in homeownership, stayed in school longer, and had greater increases in test scores among children in lower grades (Greenberg et al. 2003; Hanushek 1986). On the other hand, in the Seattle-Denver experiment, there was a surprising increase in the rate of marital dissolution, a controversial result that was not anticipated by policymakers or researchers. The negative income tax had been predicted to increase marital stability because it extended benefits to two-parent families compared to the current welfare system.

The political impact of the results of the income maintenance experiments was modest at best because political events moved too quickly (Moynihan 1973). President Richard Nixon (1913–1994) proposed a negative income tax to the U.S. Congress in 1969, long before the experiments had been completed. The plan passed the House of Representatives but failed in the Senate in 1972. Although the results of the experiments were used by the Jimmy Carter administration in formulating its welfare reform program, no negative income tax plan was ever seriously considered by Congress thereafter. When the results of the experiments were later published, the evidence of significant work reductions reinforced this lack of interest in a pure negative income tax (Greenberg et al. 2003).

LEGACY OF THE EXPERIMENTS

While the negative income tax in its idealized form has never been implemented in the United States or Canada, the idea of providing financial incentives to work has proved to be a powerful one and has led to many welfare reforms having such features. Much subsequent research
has provided stronger evidence that some families, typically those with the lowest levels of earnings, work more if given a financial incentive to do so, thereby giving more support to this idea than did the experiments. In the 1990s, many U.S. states added financial incentives to their welfare programs.

The primary alternative to financial work incentives is the idea of simply requiring work of anyone who receives benefits, a policy often characterized as using a “stick” to encourage work rather than a “carrot” of financial incentives. Such work requirements were introduced in the United States in the 1990s and have been introduced on a more limited scale in Canada in more recent years, and can be seen as directly addressing the work disincentives from unrestricted grants to nonworking families that were shown to occur in the experiments. Critics of work requirements argue that they eliminate benefits for some families who are in need but cannot work. However, a second alternative policy is an “earnings subsidy” that offers little or no grant support to nonworkers but gives a grant to those who work, possibly only those who work full-time, to provide work incentives. The U.S. Earned Income Tax Credit is the major existing policy of this type. Earnings subsidies, while providing incentives to work, also provide no support to nonworking families, who are usually in greater need. The debate on these issues continues.

The income maintenance experiments have also had a major legacy by introducing the idea of randomized trials as a method of social policy evaluation, which was a radically new idea in 1967. Since the 1970s, there have been over 250 subsequent experiments with various social policies (Greenberg and Shroder 2004). Most of these experiments have been less ambitious and of a much smaller scale than those testing the negative income tax, but they nevertheless have used the same core methodology.

INCOME TAX, CORPORATE
The corporate income tax is levied on the profits of incorporated businesses. Taxable income is defined as the gross income of a corporation minus its costs of doing business. Whereas the costs of labor and raw materials as well as interest payments are deducted from taxable income at the time they are incurred, the costs of capital assets are recovered only over time in the form of deductions for depreciation. To assess their tax liability, corporations apply a statutory tax rate to their taxable income and then subtract any deductions and other credits. The corporate income tax is mainly a central (federal) government tax, but subnational governments also apply the tax in many countries, although at a lower rate.

INCIDENCE
The effective tax rate differs from the statutory rate mainly because of the treatment of depreciation and interest payments. The effective tax burden is smaller the shorter the recovery period is and the more accelerated the rate of depreciation is. The effective burden is smaller the greater the use of debt relative to equity in financing investment because interest payments, unlike dividend payments, are expensed. The extent of the “double taxation” of dividends, first as part of corporate taxable income and then as income received by individual taxpayers, and how to address it is subject to theoretical and empirical debate.

Because labor costs are excluded in calculating taxable income, the corporate income tax generally is viewed as a tax on capital income. However, some of the tax burden
can be shifted from firms to consumers through higher prices or to workers through lower wages, depending on the structure of the product and labor markets. The closer such markets are to competitive conditions, the harder it is for firms to shift the tax burden. The empirical literature is inconclusive about the extent of that shifting.

EFFECTS

The corporate income tax can influence economic growth through its impact on economic behavior, including saving and investment. The effect on saving is ambiguous in both the theoretical and the empirical literature. The tax could affect the level and composition of capital formation by raising the cost of capital and imposing a relatively higher burden on equity versus debt financing. It also may induce firms to organize in unincorporated forms (which are not subject to corporate income tax) that may not be the economically optimal forms of organization apart from tax considerations. Moreover, tax compliance and the tax planning that businesses undertake to minimize tax liabilities, such as transfer pricing, and entail costs. The estimated costs of the distortions associated with the U.S. corporate tax fall in a wide range of one-quarter to nearly two-thirds of revenues. The tax can influence income distribution directly because taxes on capital income tend to be progressive relative to taxes on labor income and indirectly through its impact on the cost of capital.

THE CORPORATE INCOME TAX IN MAJOR INDUSTRIAL COUNTRIES AND DEVELOPING COUNTRIES

In 2003 revenue from the corporate income tax averaged around 3.5 percent of gross domestic product (GDP) among Organisation for Economic Cooperation and Development (OECD) countries. The top statutory tax rate varied substantially from 12.5 percent to 41 percent. Among developing countries that revenue averaged around 3 percent of GDP. Over the last decade or so there has been a general tendency for countries to reduce the statutory tax rate. Some countries offer corporate tax incentives in an effort to attract investment. The effectiveness of those incentives is open to debate, but incentives that provide for faster recovery of investment costs generally are considered preferable to those involving the tax rate.

INCREMENTALISM

Rejecting the rational, comprehensive model of decision-making that called for careful articulation of all goals and full consideration of all alternatives, Charles Lindblom’s essay, “The Science of ‘Muddling Through’” (1959), inaugurated a new approach to understanding public policy. While Lindblom used the term successive limited comparison rather than incrementalism, this new approach argued that: (1) means and ends are decided simultaneously, not sequentially; (2) comparisons are restricted to marginal changes in existing policy, and are not made among all possible alternatives; and (3) the appropriate test of good policy is simply the ability to make a decision. Based on both the cognitive limitations of decision makers and widespread conflicts over values in policymaking, Lindblom argued that it simply was not rational to try to make rational, comprehensive decisions.
Lindblom’s insight provided the theoretical foundation of Aaron Wildavsky’s (1930–1993) *The Politics of the Budgetary Process* (1964) and his later empirical modeling of U.S. appropriations decisions (Davis et al. 1966). As Wildavsky noted,

Budgeting is incremental, not comprehensive. The beginning of wisdom about an agency budget is that it is almost never actively reviewed as a whole every year in the sense of reconsidering the value of all existing programs as compared to all alternatives. Instead, it is based on last year’s budget with special attention given to a narrow range of increases or decreases. (Wildavsky 1964, p. 15)

Given this understanding of budget decision making, Wildavsky (1978) argued that a succession of budget reforms designed to introduce elements of rational, comprehensive choice into the appropriations process—such as President Lyndon Johnson’s (1908–1973) planning-programming-budgeting system or President Jimmy Carter’s zero-based budgeting—would inevitably fail.

The Lindblom-Wildavsky model of incrementalism was remarkably successful in inspiring a generation of research on public policymaking in general and budgeting in particular. But it also attracted considerable criticism even in its heyday. John Wanat (1974), for example, argued that the budget results reported by Wildavsky could be adequately accounted for by the prevalence of mandatory budgetary increases without reference to constraints on individual decision making or the need to coordinate decisions among political actors. John Gist (1982) then suggested that the level of competition within the budget process depended very much on the level of the budget examined. At lower levels, budgets change far more than might be expected given incremental decision making. And perhaps most telling of all, the very concept of incrementalism was characterized by considerable drift as various authors operationalized the concept in markedly different ways. Indeed, after identifying at least twelve different meanings of incrementalism used in research on public policy ranging from the “use of simple decision rules” through “smallness of ultimate change” to “absence of competition,” William Berry (1990) argued that the concept had become so broad that it should be abandoned. But none of these criticisms really slowed the pace of research on incrementalism, in large part, perhaps, because none really identified an alternative theory that could account as well for the empirical regularities reported by those working within the incremental paradigm.

Such an alternative finally appeared after renewed attention to periods of rapid policy change. Wildavsky and his colleagues (Davis et al. 1974) certainly acknowledged that, at least on occasion, policies and budgets change rapidly. But they were more attentive to the longer periods of stability than to the rarer episodes of change. But John Kingdon’s *Agendas, Alternatives, and Public Policies* (1984) drew renewed attention to the importance of episodes of sudden, dramatic change in fundamentally shaping public policy. Kingdon’s attention to nonincremental policy change was further developed by Frank Baumgartner and Bryan Jones in *Agendas and Instability in American Politics* (1993). Their punctuated equilibrium model of public policy purported to account for why we observe both short, rapid episodes of policy change and long-term stasis between such periods. Explaining how their model accounts for the former goes beyond the scope of an essay on incrementalism. But while Jones and Baumgartner’s (2005) explanation for the periods of relative stasis in policy between periods of sharp change accounts for Wildavsky’s findings, it also differs from his understanding of incrementalism. That is, rather than explaining stability by the need of politicians to find consensus in order to make any decision in the face of widespread conflict over values and the ultimate goals of public policy, the punctuated equilibrium model explains episodes of limited policy change by reference to both the government’s inability to attend to more than a few major issues at any given time and the stickiness of political institutions that inhibits rapid change. When government attention is drawn to an issue and that stickiness breaks down as veto points are overcome by political momentum, significant policy change is likely.

Has the theory of incrementalism founded on the work of Lindblom and Wildavsky really been surpassed? It is clear that the theoretical analysis used to account for observations of incremental behavior has shifted from attention to the limited cognitive capacities of individuals and the necessity of politicians to make decisions in the face of conflicting values to the stickiness of political institutions and institutional limits on the size of policy agendas. And it is also true that scholars are now more attentive to the importance of periods of rapid change that are observed in most policy areas over time. In these senses, the theory of incrementalism has been surpassed by Baumgartner and Jones’s theory of punctuated equilibrium. But in other respects, incrementalism is alive and well. Baumgartner and Jones’s attention to periods of punctuation is important largely because most policymaking, most of the time, is incremental in the sense used by Wildavsky in the quotation presented at the beginning of this essay. Most policy decisions are not reexamined every year against all possible alternatives. The backdrop of punctuations is as important as the punctuations themselves. Even more importantly, neither Kingdon’s policy
agendas model nor Jones and Baumgartner’s punctuated equilibrium model represents a return to the model of rational, comprehensive decision making so strongly rejected by Lindblom and Wildavsky.

INDIAN NATIONAL ARMY

The Indian National Army (INA) was formed in 1942 by Indian prisoners of war captured by the Japanese in Singapore. It was created with the aid of Japanese forces. Captain Mohan Singh became the INA’s first leader, and Major Iwaichi Fujiwara was the Japanese intelligence officer who brokered the arrangement to create the army, which was to be trained to fight British and other Allied forces in Southeast Asia. The Japanese had sent intelligence agents to Southeast Asia from the late 1930s onward, and they made contact with the considerable population of South Asians resident in Malaya, Singapore, Thailand, Burma, and other parts of the region. The Japanese aim was to use and benefit from the nationalism of Asian peoples in constructing what they called their “Greater East Asia Co-Prosperity Sphere.”

With the opening victories in the war, from December 1941 through the early months of 1942, the Japanese captured large numbers of Indian prisoners, particularly in their victory at Singapore in February 1942. Some 40,000 to 50,000 men were recruited for a training corps of South Asian residents in Southeast Asia.

With the help of Rash Behari Bose, an Indian nationalist long resident in Japan, the civilian Indian Independence League (IIL) was formed to support the INA and push for Indian independence. This organization provided vital support for the INA throughout the war period. For example, one member in Burma traded liquor for medical supplies desperately needed by the INA.

Tensions developed in late 1942 between Mohan Singh and the Japanese over terms of cooperation. The Japanese were determined to exercise control over the INA and push for Indian independence. This organization provided vital support for the INA throughout the war period. For example, one member in Burma traded liquor for medical supplies desperately needed by the INA.

Tensions developed in late 1942 between Mohan Singh and the Japanese over terms of cooperation. The Japanese were determined to exercise control over the INA that Mohan Singh was not willing to accept. He was relieved of command and imprisoned. Rash Behari Bose was still in good standing with the Japanese, but he had no popular following. A more charismatic leader was needed. In May 1943 Subhas Chandra Bose, a leading Congress nationalist from Bengal who had been working in Germany, arrived in Southeast Asia via a German and then a Japanese submarine, and he provided the leadership that was needed. He became commanding officer of the INA and also set up a provisional government of free India, which was recognized by the Axis powers. The main training camp of the INA was in Singapore, and young
women from the South Asian community in Southeast Asia were recruited for the women's regiment, called the Rani of Jhansi Regiment. It was headed by a young medical doctor, Lakshmi Swaminathan, who also became minister for women's affairs in the provisional government. Bose worked carefully to get soldiers from all communities—Hindus, Muslims, and Sikhs—to cooperate for the greater good of Indian independence.

In late 1943, Bose persuaded the Japanese to attempt an invasion of India from Burma, with the INA as a small force working alongside the Japanese's main invading force. This effort succeeded in breaking into India near Imphal in 1944. However, the Japanese overextended their supply lines and had no air cover. In their opening victories of the war, the Japanese had good air cover and succeeded in capturing British supplies as they advanced, but now the battles in the Pacific and elsewhere had deprived them of most of their air force. The Allied forces, headed by General William Slim of Great Britain, retreated at first, by design, but then attacked and drove the Japanese and the INA from India and back through Burma. Both the Japanese and the INA suffered greatly from disease and starvation as they retreated. Though the INA fought bravely overall, some men surrendered, and the remaining troops were eventually captured as the British, Indian, and American forces triumphed in Southeast Asia in the spring and summer of 1945.

Subhas Bose attempted to escape to Manchuria and was in a Japanese plane that crashed after take-off in Taiwan in August 1945. The evidence shows that he died of his burns and was cremated there. There was one Indian survivor of the plane crash, Habibur Rahman, and several Japanese survivors, in addition to the doctor who treated him, all of whom testified on several occasions to the story of the crash and his death. However, some Indians chose for decades not to believe the account for personal and political reasons. His ashes were taken to Tokyo and lodged in a Buddhist temple where they remain.

Three officers of the INA, Shah Nawaz Khan (a Muslim), Prem Sahgal (a Hindu), and G. S. Dhillon (a Sikh), were tried for offenses against the King-Emperor in 1945–1946 in the Red Fort in Delhi. The British miscounted by putting an individual from each religious community on trial, however, and there were massive demonstrations throughout India. As a result, although they were convicted and sentenced to transportation for life, they were soon released. The support the public showed for these rebel military men was one factor in the British government's decision to grant independence to India in 1947.

INDIAN NATIONAL CONGRESS

Founded in 1885, the Indian National Congress (INC) was at the forefront of the nationalist movement in India before 1947. After India's independence in that year, the Congress emerged as the ruling party, and it maintained power uninterrupted for three decades (1947–1977). Since then, the party has been in and out of power.

In the first three decades of its existence, the Congress was an elite organization dominated by English-educated, urban middle-class Indians. The organization was much like a debating society, but Mohandas K. Gandhi, who assumed its leadership in 1920 and remained its spiritual leader until his death in 1948, transformed the Congress into a mass movement and a political institution with an organizational structure that paralleled the colonial administration. Gandhi expanded the membership and appeal of the Congress by mobilizing the rural population, especially the lower castes and outcastes of the Hindu social hierarchy—the sudras, or “untouchables.” The Congress became the sole representative of the national cause, leading three campaigns between 1920 and 1947: the noncooperation movement (1920–1922), the civil disobedience campaign (1931–1932), and the “Quit India” movement (August 1942). The Congress won seven of the eleven provinces in the 1937 elections, which were held under British rule following the provisions of the Government of India Act of 1935, and it formed a government in those provinces.

After independence the Congress, hitherto an all-embracing national movement, was transformed into a political party. Under the leadership of Jawaharlal Nehru, India's first prime minister (1947–1964), it retained the character of an eclectic political organization with a wide
range of positions. The Congress controlled 70 percent of seats in parliament and held power in most states between 1951 and 1967. This period of one-party dominance has been referred to as the Congress “system” in Indian politics. However, the power struggle between Indira Gandhi (Nehru’s daughter, who was prime minister from 1966 to 1977 and 1980 to 1984) and the Congress organization led to the party split in 1969. The majority followed Mrs. Gandhi to her “New Congress” or “Congress (R)” (R for “ruling”), which was recognized by the election commission as the “real” INC. Mrs. Gandhi’s leadership of the Congress led to the deinstitutionalization of the party as she undermined the federal character of the party by stopping party elections and concentrating power in her own hands.

The Congress lost its dominant position for the first time in ninety years with its defeat in the 1977 elections, held after the unpopular Emergency Rule Mrs. Gandhi had imposed in 1975. Faced with criticism of her leadership, Mrs. Gandhi split the party a second time, in 1978, and formed the breakaway Congress (I) (I for “Indira”). The Congress (I) returned her to power in 1980, but she was assassinated in 1984. Mrs. Gandhi was succeeded by her older son Rajiv Gandhi (1944–1991), who lost power in the 1989 elections. When Rajiv Gandhi was assassinated in 1991, the party presidency was offered to his widow, Sonia Gandhi (b. 1946), who declined the offer. Although the party held power from 1991 to 1996, the Congress was in decline as a national party due primarily to the lackluster leaderships of P. V. Narasimha Rao (1921–2004) and Sitaram Kesri (1919–2000). In 1998 Sonia Gandhi was elected party president and started rebuilding the party, especially by expanding its support base among Muslims and the poor. Her leadership did not help the party win the 1999 elections, and a small number of Congress (I) leaders led by Sharad Pawar (b. 1940), who questioned the likelihood of foreign-born Gandhi becoming prime minister, formed a breakaway party in 1999 (the Nationalist Congress Party). Nevertheless, Gandhi’s leadership energized and revitalized the Congress (I) Party. In the 2004 parliamentary elections the Congress won enough seats to form a coalition government with the support of about a dozen center-left parties. Gandhi, however, declined to become prime minister; instead she remained the party president, and Manmohan Singh (b. 1932) became prime minister. The Congress expects that Rajiv and Sonia’s son Rahul Gandhi (b. 1970), who won a parliamentary seat in 2004, will play a significant role in the party in the near future.

Indigenismo

Spanish) in Latin America by outsiders (called indigenistas). It is a uniquely American phenomenon, and its origins are inextricably bound together with debates on the question of how colonized indigenous peoples should be treated. Its importance as a philosophical aspect of Latin American thought dates to the beginnings of European attempts to subdue the aboriginal inhabitants of the American continent in the late fifteenth century. It reached its high point in the early twentieth century in countries with high concentrations of indigenous peoples, particularly Mexico and Peru. Although its characteristics changed over time, indigenismo always presented a critique of indigenous issues from an elite, educated, urban perspective rather than from that of the indigenous peoples.

The Dominican priest Bartolomé de las Casas (1484–1566) presented the earliest articulate defense of indigenous rights from a European perspective. But he retained loyalty to the Catholic Church and to the Spanish Crown, and ultimately the purpose of his efforts was for the conversion of indigenous peoples to Christianity and their assimilation into the Spanish kingdom.

Modern indigenismo first emerged in the nineteenth century and was characterized by romantic and humanitarian impulses. This indigenista discourse came to be dominated by intellectuals who were strongly influenced by Spencerian positivist thought meant to assimilate the surviving indigenous peoples in the Americas into a dominant Spanish or Portuguese culture. Indigenismo particularly gained strength in Mexico in the aftermath of the 1910 revolution because it embraced the country's glorious indigenous past while assimilating their descendants into a unified mestizo nation.

By the 1920s indigenismo had become a form of protest against the injustices that Indians faced. Political parties, especially populist ones, began to exploit indigenista ideologies for political gain. Indigenismo flourished in the 1930s, particularly in Peru and Mexico, and in the 1950s it was institutionalized in the Guatemalan and Bolivian revolutions. With officialization, indigenismo lost its revolutionary potential to improve the lives of Indians. Elite mestizo intellectuals and leftist political leaders led this movement, which they often used only to advance their own political agendas.

Indigenismo often emerged out of anthropological and archaeological studies. Manuel Gamio (1883–1960) was both a pioneer anthropologist and indigenista in Mexico who reconstructed archaeological sites for tourists, including Teotihuacán north of Mexico City. Although indigenistas proudly championed the ancient Aztec and Inca civilizations, they often ignored or discounted their present-day descendants.

Peruvian Marxist José Carlos Mariátegui is one of the best-known indigenista intellectuals. In Seven Interpretive Essays on Peruvian Reality (1928), Mariátegui criticized various strategies that others had employed to improve the lives of indigenous peoples, including humanitarian campaigns, administrative policies, and legal reforms. He argued that their problems were rooted instead in the nature of the land-tenure system, and that only through fundamental economic change and land reform would social improvements be possible. Mariátegui was an indigenista in the classical sense in that he was an urban mestizo intellectual who had little contact with Peru’s indigenous peoples, but he did not portray the worst elements of paternalism and assimilation common to indigenismo.

Indigenismo was also represented in literature, particularly in well-known novels such as Jorge Icaza’s Huasipungo (1934) in Ecuador or Rosario Castellanos’s Balún-Canán (1957) in Mexico. Typically, such novels focused on the oppression of poor indigenous agricultural workers at the hands of large landholders, depicting indígenas as primitive and ignorant people who are unable to improve their lives without outside assistance. The solution, when one is offered, is that through education they might be elevated and assimilated into the dominant culture; rarely are indigenous cultures recognized as valuable and worthy of protection. In art, the paintings by the Mexican artists Frida Kahlo (1907–1954) and Diego Rivera (1886–1957) utilized indigenous themes to advance their leftist political ideologies.

In 1940 the Mexican president Lázaro Cárdenas (1895–1970) organized the First Inter-American Indigenist Congress at Pátzcuaro in the state of Michoacán. Delegates were anthropologists and sociologists as well as religious workers and high government officials such as John Collier, the architect of Franklin D. Roosevelt’s Indian policy in the United States. The Pátzcuaro Congress broke from colonialist thought, but its tone was still integrationalist. The Instituto Indigenista Interamericano (III, Inter-American Indigenist Institute) that emerged out of the Pátzcuaro Congress was based in Mexico City, and Gamio served as its first director. The III held congresses about every five years, and indigenistas formed national branches in many of the American republics. In addition to publishing the journals América Indigenista (later renamed Anuario Indigenista) and Boletín Indigenista, the III became an official organ of the Organization of American States (OAS).

In 1971 eleven anthropologists gathered in Barbados for the Symposium on Inter-Ethnic Conflict in South America. Their Declaration of Barbados demanded the liberation of indigenous peoples from colonial domination, specifically calling for the defense of indigenous culture and territory, the establishment of economic, social, educational, and health assistance, and support for a native-led pan–Latin American movement for self-government.
As indigenous peoples began to build their own organizations, they presented a sustained critique of indigenismo as a construction of the dominant culture, a paternalistic impulse designed to stop liberation movements. Indigenous peoples criticized academics who studied their cultures without returning any political benefits to their communities. Rather than letting outsiders appropriate indigenous cultures and concerns for their own purposes, indigenous leaders insisted that they could represent themselves. Particularly strong indigenous political movements emerged in countries with relatively weak indigenista traditions such as Ecuador and Guatemala. By the end of the twentieth century indigenous leaders had created a neoindigenismo that advanced their own political agendas.

INDIGENOUS RIGHTS
Indigenous rights are those legal and moral rights claimed by indigenous peoples. But what is meant by “indigenous peoples,” and in what sense are their rights peculiar to them? From what source do these rights flow? Are they legal rights granted by the state, or are they moral rights that have yet to be established in law? Or are they human rights, derived from those basic rights ascribed to human beings everywhere? The situation of indigenous peoples also raises further questions about the nature of these rights: Are they individual rights or group rights, social and political rights or cultural rights? And finally, against whom or what are they claimed? The state within which they live, or the international community as a whole—or both?

INDIGENOUS RIGHTS AND THE HISTORY OF COLONIZATION
But first, who counts as an indigenous people? This is a complex and politically loaded question, both in domestic and international contexts. First of all, there are disputes over who or what counts as “indigenous.” Secondly, there are disputes over who counts as a “people” in international law, especially when it comes to ascribing and distributing the right to self-determination. There are two basic approaches to the question of indigeneity. First, one can link indigeneity to literal first residency or occupation of a particular territory. Contemporary indigenous peoples in this case would be descendants of the earliest populations living in that area. Second, one can tie indigeneity to those peoples who lived in that territory before settlers arrived and the process of colonization began. This relativizes the definition to prior occupation rather than first occupation. Although there is enormous diversity among the many different indigenous nations in the world, another common dimension to their self-description as indigenous is the connection to land; as James Anaya has put it, they are indigenous in the sense that “their ancestral roots are embedded in the lands in which they live … much more deeply than the roots of more powerful sectors of society living on the same lands” (Anaya 1996, p. 3). Still, the term remains unsettled in international law and domestic practice. Given the diversity of peoples in question and the complexity of circumstances in which the claims are being made (for example, not just in the Americas and Australasia, but also in South and Southeast Asia), many have argued that indigeneity should be interpreted in as flexible and “constructivist” a manner as possible (Kingsbury 1998; 2001).

From the perspective of indigenous peoples at least, it is important to distinguish their claims from the claims of other minority groups, such as migrants or refugees, because they are challenging the extent to which their incorporation into the state (and its subsequent consequences) was just. The question of legitimacy looms much larger with regard to indigenous peoples than it does with other minority groups. Often precisely because their claims are distinct in this way they are controversial. They challenge liberal conceptions of distributive justice and the underlying conceptions of equality and individual rights that tend to presuppose the legitimacy question is moot. Although they challenge these conceptions, it is not clear that the claims of indigenous peoples are fundamentally incompatible with them (Kymlicka 1989, 1995; compare Barry 2001, Alfred 1999). However, the historical experience of indigenous peoples in the course of the development of liberal democracy in the Americas and Australasia suggests that the challenges they face are profound. Hence the ambiguity surrounding the appeal to the language of rights.
The history of European colonization and its impact on the indigenous inhabitants of the Americas and Australasia is by now depressingly familiar. Indigenous populations were displaced and removed from their traditional lands; they were dramatically reduced in size and strength through disease, war, and the consequences of European settlement and forced removals; and their legal and moral rights to exercise self-government over their territories were subsumed under the authority of the newly established states. In the United States, for example, although Justice John Marshall in a series of landmark cases in the nineteenth century recognized the limited sovereignty of the American Indian nations (as “domestic dependent nations”), they were ultimately subject to the plenipotentiary power of Congress. Thus, although Native American tribes in the twenty-first century are able to exercise various forms of jurisdiction and claim ownership over some of their (much reduced) tribal lands, they remain subject to both state and federal law in significant respects. Similarly, in Canada, Australia, and New Zealand, although within a different jurisprudential framework, indigenous nations are able to exercise only limited forms of self-government (if any), and are able to claim ownership (“aboriginal” or “native” title) over an extremely small proportion of their former territories. In all of these places, indigenous people also tend to suffer from appalling social and economic hardship; they are amongst the poorest, sickest, most unemployable, and most incarcerated members of the population. They tend to have higher infant mortality rates and shorter life spans, and to suffer disproportionately from the effects of alcohol and drug abuse and domestic violence. In many cases, indigenous children were at various times either forcibly removed from their families or enrolled into residential schools, where often they suffered from abuse. And yet, despite this legacy of historical and enduring injustice, indigenous cultures and communities, as well as indigenous political activism, has persisted, in both domestic indigenous cultures and communities, as well as indigenous rights are a species of these kinds of claims. This might also lead one to emphasize the distinctive source of indigenous legal and moral rights—the hundreds of treaties that were signed between the various indigenous nations and European settlers in the Americas, for example, from the fifteenth century onward. The treaties themselves, as well as the normative framework of recognition, negotiation, and consent that they supposedly represent, offer both a legal and moral framework of recognition, negotiation, and consent that they supposedly represent, offer both a legal and moral framework. Moral rights are those rights that are grounded either in some purportedly valid moral claim, or with reference to some broader moral framework, but which are not necessarily established in law. We often appeal to moral rights in order to criticize existing practices and laws. Indigenous rights are asserted in both senses. Indigenous people argue that their rights are not merely derivative from the state, but rather are justified in relation to their own political theories and practices and more general moral arguments. This is distinct from the claim that in order to become effective, rights must eventually be recognized and enforced by the state, or some other effective set of legal and political institutions.

Rights are not self-justifying. They are used to mark out certain crucial interests or capacities of individuals (and sometimes groups) that it is thought deserves special kinds of moral and legal attention. But claims about the interests or capacities they refer to must be justified, and that means drawing on potentially controversial moral claims, which are often subject to change over time as societies and attitudes change. A challenge facing anyone defending indigenous rights is in making clear what work the modifier “indigenous” is doing. To what interests or capacities do these rights refer? One the one hand, one can appeal to the historical, cultural, and political specificity of the interests at issue—to indigenous difference, in other words. This might also lead one to emphasize the distinctive source of indigenous legal and moral rights—the hundreds of treaties that were signed between the various indigenous nations and European settlers in the Americas, for example, from the fifteenth century onward. The treaties themselves, as well as the normative framework of recognition, negotiation, and consent that they supposedly represent, offer both a legal and moral framework of recognition, negotiation, and consent that they supposedly represent, offer both a legal and moral framework of recognition, negotiation, and consent that they supposedly represent, offer both a legal and moral framework. Moral rights are those rights that are grounded either in some purportedly valid moral claim, or with reference to some broader moral framework, but which are not necessarily established in law. We often appeal to moral rights in order to criticize existing practices and laws. Indigenous rights are asserted in both senses. Indigenous people argue that their rights are not merely derivative from the state, but rather are justified in relation to their own political theories and practices and more general moral arguments. This is distinct from the claim that in order to become effective, rights must eventually be recognized and enforced by the state, or some other effective set of legal and political institutions.

A second approach, then, is to appeal to more general rights, and especially human rights, and to argue that indigenous rights are a species of these kinds of claims. Thus they refer to interests or capacities that everyone, indigenous or not, deserves to have protected or promoted. Reference to indigenous rights here is a pragmatic move; it is intended to extend to indigenous peoples those
Indigenous Rights

rights to which they have always been entitled, but denied for contingent historical and political reasons.

Of course, these two approaches overlap and are often combined. For example, the Canadian Royal Commission on Aboriginal Peoples (1996), charged with outlining a new vision for relations between Canada’s “First Nations” and the state, drew on a normative vision they associated with the historical practice of treaty making. According to this argument, indigenous rights draw on a body of intersocietal law and practice based on those rights originally recognized between aboriginal nations and European powers at the time of European settlement, as well as more general moral and political claims to do with equality and freedom.

INDIVIDUAL RIGHTS, GROUP RIGHTS, AND COLLECTIVE RIGHTS

A fundamental question about the nature of indigenous rights is the extent to which they include not only individual rights but also group rights. To be sure, some individual rights enable or promote collective activities and public goods; for example, the right to freedom of association, or to religious freedom, or to a democratic say in government. And some individual rights can be distributed on the basis of group membership; these can be seen as “personal” collective rights, or “membership rights” (Appiah 2005).

Do indigenous peoples have collective rights in this sense, or in terms of a right possessed by the group or nation as a whole, as opposed to the individual members? Part of the concern is that promoting or protecting individual rights might not offer enough protection from the harms indigenous peoples have suffered from over the years, and might not suit the distinctive kinds of interests they seek to protect. Indigenous land rights, for example, are often thought of as a group right because “aboriginal title” inheres in the group as opposed to the individual members, given the distinctive conceptions of land within indigenous worldviews (although the relation between the collective title and individual entitlements under it are complex). The right to self-determination is also sometimes conceived as a group right, just insofar as it can only be exercised jointly by the group as a whole. If indigenous peoples have a moral and legal right to self-determination—as has been proposed in the Draft Declaration of Indigenous Rights (1993)—and the right to self-determination is a basic human right, then arguably there is at least one collective human right. But the right to self-determination is itself a deeply unsettled and contested doctrine in international law and normative political theory (Buchanan 2004). The best justification of the right to self-determination is one that embeds it within the constraints of broader individual human rights, as well as detaching it from any necessary association with statehood. In fact, the political activism of indigenous peoples in international fora has helped to promote new thinking about the nature of self-determination more generally (Kingsbury 2001). It is the creative use of the practice of rights by indigenous peoples that is most striking about the emergence of “indigenous rights.” They have used it to gain access to political debates and exert their political agency. And they have managed to turn around a discourse that was once used mainly to discriminate against them into one of the key tools of their struggle against enduring injustice.

**INDIRECT RULE**

Within colonial discourse, *indirect rule* designates a British system of African governance through indigenous chiefs, usually contrasted with French *assimilation*, a more centralized policy of transforming colonial subjects into replicas of European citizens. Historically, indirect rule can be understood in several ways: as an expedient of all modern colonial regimes; as an explicit British doctrine; and as the political dimension of a twentieth-century colonial syndrome that included the social sciences.

Although *indirect rule* might describe any exercise of imperial power through the agency of local authorities, the concept best applies to the colonialism that emerged with the establishment of British and Dutch rule in India and Indonesia during the latter 1700s. In these situations, a relatively small number of European officials took charge of territories with populations consisting of indigenous peoples rather than immigrant settlers or slaves. Most such governments, whether in Asia or Africa, would be “indirect” to some degree, that is, heavily dependent upon local auxiliaries. In no cases (except the very tiny French colonies that survived British conquest before 1815) were efforts made to assimilate the entire population to European culture and political status. In the larger colonial territories (including later-acquired French ones), the only choices were between the proportion and status of native auxiliaries who would either be co-opted from existing structures of authority or created anew via European schooling. Even these distinctions were not always clear: hereditary rulers could be given a European education or assigned a new role (as were provincial landlords in eighteenth-century Bengal and twentieth-century Uganda) based on European precedents. Moreover, all colonial administrations depended heavily upon European-educated clerks and interpreters, who held very low formal positions.

The British doctrine of indirect rule emerged in Africa during the early 1900s when the conqueror of Northern Nigeria, Lord Frederick Lugard (1858–1945), incorporated the local Sokoto caliphate into his new regime. Both Lugard and later historians linked this mode of administration to the already-established practices of upholding princely states in India. However, the major princely states, which remained separate for at least internal administrative purposes from British India, were far larger and more powerful than even the Sokoto caliphate, unique in tropical Africa for its degree of bureaucratic development. Moreover, indirect rule was extended throughout British Africa to much less articulated states and chieftoms, even including, in the 1920s and 1930s, *joint native authorities* based on village councils. In contrast to the princely states (which might better be compared to protectorates of the short-lived League of Nations mandates established by the French and British throughout the Middle East), indirect rule involved continuous intrusion by European administrators into the internal affairs of local rulers through such standardized and highly transparent institutions as native treasuries and native courts.

Indirect rule rested upon a combination of conservatism and paternalist liberalism. Its overseas political goal—which ultimately failed—was to slow and “traditionalize” movements toward decolonization. Among European administrators and their domestic audience it became the center of a new colonial orthodoxy (even France abandoned assimilation for the more vague *association*). The “native,” rather than economic gain, was to be the center of concern and was approached with a degree of cultural relativism. Mid-nineteenth-century India here became an anti-model in which aggressive British policies had produced both the Revolt of 1857 and a more enduring class of European-educated *babus* (actual or would-be native government employees). Reluctance to undermine any more indigenous rulers or landlords was one result of this retreat from direct rule/assimilation, but so was withdrawal of support for indigo planters in Bengal, new ideas about education, and programs of village-based anthropological research. All these concepts extended into newer colonies in Africa and (to a lesser extent) the Pacific and Southeast Asia.

Indirect rule, beliefs in peasant versus plantation economies, adapted education, and anthropology all came together in the International Institute for African Languages and Cultures (IIALC, now the International African Institute), founded in 1926. Lugard and similarly minded French and Belgian colonial administrators served as directors of the IIALC. The other founders were missionaries who joined with colonial officials in blocking white settler ascendancy in British East Africa. The most immediate concern for missionaries, however, was education, which they believed had to be less “literary” and European and undertaken in African languages (the anti-clerical French Third Republic balked on the language
issue, producing a key difference between the two colonial heritages).

The rising new school of functionalist social anthropology used the IIAC's journal *Africa* as a platform to publish its research, assert its relevance to indirect rule and related policies, and launch a successful campaign for funding from the U.S. Rockefeller Fund. In reality, most of the ethnography used to implement indirect rule in Africa (as had been the case earlier in India) was done by administrators and missionaries. Indirect rule was thus more important for the development of social science (in France as well as Britain) than academic anthropology proved to be for colonialism.

**INDIVIDUALISM**

The term *individualism* covers a range of ideas, philosophies, and doctrines that emphasize the unlimited freedom of the individual and the individual’s right to protect his or her own interests against those of society. The French liberal writer Alexis de Tocqueville (1805–1859) coined the word to characterize individual selfishness—a value system that predisposes human beings to be concerned only with themselves and their small circle of family and friends. Arising in reaction to the collectivist spirit of the Enlightenment and the French Revolution, its original meaning tended to be rather negative and controversial, implying that individualism was a source of social atomism, anarchy, and public disorder. Thus, while praising the individualism of nineteenth-century America, Tocqueville at the same time cautioned against its threat to public life through the weakening of social bonds and obligations.

**LIBERAL INDIVIDUALISM**

Today the term is often employed to describe a political and social philosophy—sometimes referred to as “liberal individualism” or “laissez-faire individualism”—that stresses the primacy of the individual and the importance attached to individual freedom, self-reliance, privacy rights, and individual choice. In its full-fledged form, it emerged first in Britain with the spread of the laissez-faire ideas of Adam Smith (1723–1790) and the utilitarianism of Jeremy Bentham (1748–1832) in economic and political theory. In the Anglo-Saxon world, liberal individualism became a catchword for free enterprise, free markets, limited government, and unrestricted economic freedom, as well as for the individualistic attitudes, forms of behavior, and aspirations that sustain the idea of “self-made man.” One influential version of this usage was U.S. president Herbert Hoover’s campaign speeches in 1928 celebrating “rugged individualism” in America. Above all, individualism came to signify a preference for a minimal government role in social, economic, and religious affairs, as exemplified by the slogan “That government that governs least governs best”—though not in matters of public morality or law and order—as opposed to the more collectivist ideals of socialism.

Individualism is frequently contrasted with collectivism, a social philosophy in which the collective or common weal rather than the individual good is considered paramount. Man is seen in the Aristotelian tradition as a social animal, whose very nature, wants, and capacities are to a very large extent the product of society and its institutions—running the gamut from the workplace and all kinds of voluntary associations to the nation-state and the global market. For example, the famous Enlightenment philosopher Jean-Jacques Rousseau (1712–1778) advocated subordinating the individual will to the collective will, a view that is in fundamental opposition to the philosophy of individualism. Rousseau’s popular treatise *Social Contract* (1762) maintains that each individual is under an implicit contract to submit his or her will to the “general will” of the entire citizenry (volonte generale), although the “general will” need not be the will of absolutely all citizens (volonte de tous).

In his major work *Democracy in America* (1835, 1840), Tocqueville himself took a rather ambiguous stand about individualism, at times giving it a distinctly pejorative flavor. He was torn between his admiration for the individualism of American democracy and his anxiety about its political implications, such as the danger of widespread social conformism. He pointed to two major aspects of the individualistic character of American society—on the one hand, a faith in individual reason as the sole basis of public opinion, and, on the other, a self-centered, self-interested preoccupation with private concerns.
This second aspect of American individualism manifested itself in pervasive egoism, a widespread tendency to withdraw from public affairs and to focus on the material welfare of the family as the most important purpose in life. This egoism was evident in unrestrained personal ambition and atomistic competition. In a society where the scramble for power and possession was widely thought to be open to all—and failure could not be ascribed to disadvantages of birth or any other privilege—the contest was bound to be fierce and uncompromising. Tocqueville believed that individualism could pose a threat to liberty, because individualistic attitudes encourage individual subservience to public opinion and conformism. U.S. democracy found its source of intellectual authority in prevailing public opinion based on the idea of the moral equality of all individuals. The conformity to generally held attitudes and social standards was thus the result of the imposition of social sanctions by one's peers. When Tocqueville asked why there were no professed atheists in the United States, his answer was that atheists would not get any jobs or customers. When faced with the opinion of the majority, the individual felt powerless: If the majority of one's equals is always right, then a dissenting opinion must be always wrong. For Tocqueville, this conformist attitude was an assault on individual liberty—a "new kind of despotism" over isolated individuals too afraid of public opinion to object, too absorbed in private concerns to participate in public activity, too aware of the economic value of public order to threaten protest and disorder. Such "tyranny of the majority," the Frenchman warned, would weaken not only liberty but the very will to liberty.

Tocqueville's warnings about the paradoxical contradictions of individualism have been echoed numerous times in modern social and cultural criticism. The philosophy of liberal individualism has been criticized for creating a culture of what Canada's most eminent political theorist, C. B. Macpherson (1911–1987), called "possessive individualism," a theory of human nature that is rooted in the seventeenth century and is based on "a conception of the individual as essentially the proprietor of his own person or capacities, owing nothing to society for them" (Macpherson 1962, p. 3). Such a society, according to Macpherson, where individual skills are a commodity to be bought and sold on the open market, demonstrates a selfish and unrestricted thirst for private consumption that is celebrated as the very essence of human nature. The American sociologist Robert Bellah (1985) has similarly warned that individualism is becoming so pervasive and excessive in the United States that it is destroying the integrity and moral foundations of American society.

During the nineteenth century and the early twentieth century, economic individualism in the form of laissez-faire capitalism came into conflict with political individualism in the form of representative democracy, as the newly enfranchised working-class voters increasingly came to demand government intervention in the marketplace far beyond the mere enforcing of economic contracts. The rise of militant labor unions and the mass socialist parties built upon them made free-market economic policies morally untenable and politically risky, especially after the 1917 Bolshevik Revolution in Russia. The worldwide Great Depression of the 1930s and the governmental response to it based on the interventionist theories of John Maynard Keynes (1883–1946), the preeminent British economist who revolutionized the science of economics by advocating active state involvement in the capitalist economy, ushered in the collectivist-inspired "social-welfare state" and also seemed to sound the death knell for the discredited doctrines of economic individualism. But the waning of western social democracy and the decline and eventual downfall of Soviet-style "state socialism" in the late twentieth century led to the revival of the ideas of laissez-faire capitalism—first during the era of Thatcherism in the United Kingdom and Reaganism in the United States, and later with the neoliberal policies of "globalization capitalism." The anti-Keynesian and anti-statist writings of Ludwig von Mises (1881–1973), Friedrich von Hayek (1899–1992), Milton Friedman (1912–2006), and their followers have also contributed to restoring the previously tattered intellectual reputation of economic individualism.

**METHODOLOGICAL INDIVIDUALISM**

In another widespread, although thematically separate usage, the so-called "methodological individualism" in the social sciences refers to the position adopted by those who argue that groups (collectivities) are nothing more than their individual members. In this view, there are no properties of groups that are not reducible to individual properties. Not only must scientists study individuals, but also the explanations of the social phenomena they study—phenomena such as social class, power, the political system, and so on—must be formulated as, or be reducible to, the characteristics of individuals. While not denying that groups exist, the individualist does deny that they have any independent status and that they are more than the sum of their parts. As former British prime minister Margaret Thatcher famously declared, "There is no society, only individuals."

This individualistic position stands in marked contrast to the so-called "methodological holism," the theoretical principle that each social entity (group, institution, society) has a totality that is distinct and cannot be understood by studying merely its individual component elements. There are emergent group properties that are not reducible and, therefore, groups (collectivities) are more than the sum of their parts. For example, the famous

French sociologist Émile Durkheim (1858–1917) claimed that collective phenomena are not reducible to the individual actor or psyche; hence, social facts can be investigated and explained independently of the individual. The debate over methodological individualism versus methodological holism in the social sciences reflects an underlying ideological tension about the relationship between the individual and society, recognizing that these two analytical levels are distinct and may have to be explicated separately.

INDUSTRIALIZATION
Industrialization refers to a broad process through which industry displaces agriculture and assumes a dominant role in a society’s economy. It involves the extension of commodity production on a large scale and the emergence of wage labor as the principle mechanism for the organization of work.

Historically, this shift has often come with a number of concomitant changes, including the formation of a united territory, where the state either created a legal system to protect property rights or directed the industrialization process itself; an increase in agricultural productivity, allowing a surplus population move into industry; the diffusion of scientific knowledge and technological know-how; the creation of a workforce socialized into an ethos of time discipline; and a willingness of investors or the state to commit large funds to industry rather than to speculation, plunder, or military expenditure.

EARLY THEORIES OF INDUSTRIALIZATION
Industrialization began in Britain at the end of the eighteenth century, and it soon spread throughout Europe, North America, and Japan. However the process was profoundly uneven, particularly as countries combined elements copied from the more advanced regions with their own traditional social practices. In his classic 1969 account of the French “paradox,” Tom Kemp argued that while the Revolution of 1789 created the most favorable legal conditions for capitalist development, it also, ironically, allowed the peasantry to stay more rooted to the land and gave small-scale preindustrial forms of capitalism new opportunities for commercializing agricultural products. On a more general level, Alexander Gerschenkron claimed that backwardness (essentially defined as a divergence from the British model) led to a “tension” that was only resolved when larger institutions such as banks intervened to mobilize scarce capital for an industrialization project. In the case of Germany, for example, the banks helped create an “organized capitalism,” through which investment was concentrated in coal mining, iron and steel-making, electrical and general engineering, and chemical plants. Earlier industries that had played a key role in Britain’s development, such as textiles, were of fringe interest because the banks strategically concentrated on new lead industries.

The pressure to industrialize, when combined with a scarcity of capital and a lack of domestic markets, also led to the intervention of another key player: the state. For Adam Smith and the neoclassical school, the only role assigned to the state was that of the famous “night watchman,” who patrolled the perimeter of the economy guar-
anteeing property rights and security. Subsequently, many writers have questioned this minimalist role. For Ernest Gellner, writing in the 1980s, the very social and geographical mobility that industrialization required forced the state to take measures to standardize the cultural outlook of its population through the introduction of national curricula in schools. Gerschenkron went further, arguing that a stronger state role might be needed to break the barriers of stagnation. Merely providing the promise of rewards for entrepreneurial efforts might not be enough. Writing in a decade when China was still an impoverished rural society, he noted that “capitalist industrialization under the auspices of socialist ideologies may be, after all, less surprising a phenomenon than would appear at first sight” (Gerschenkron 1952, p. 25).

In what the American economist Paul Krugman has called the period of “high development theory,” in the late 1940s and 1950s, there was a consensus that a “visible hand” was necessary to propel a country towards industrialization. The Polish economist Paul Rosenstein-Rodan noted in 1943 that balanced growth and a “big push” were also required. Balanced growth was needed so that a complementarity of demand would reduce risk in investment. When investment occurred on a wide front, new producers could become each other’s customers, thus reducing the risk of not finding a market. In addition, the state had a key role to play in developing infrastructure and training a workforce. While the concept of “balanced growth” was questioned by Albert Hirschman in 1958, the consensus was that industrialization would emerge from increased savings directed by the government to industry.

DEPENDENCY THEORY
Outside the field of conventional economics, a more radical critique of Smith’s neoclassical model also developed. Starting with Raul Prebisch, who led the United Nations Economic Commission for Latin America and the Caribbean (ECLAC) from 1948 to 1963, this critique emphasized the wider structural relationships into which poorer countries were inserted. Prebisch and the other dependency theorists claimed that the nations on the periphery were often forced to supply primary produce to metropolitan countries in return for industrial and consumer goods. Far from gaining a comparative advantage by specializing in exporting products where they had natural advantages, however, they had to produce ever more primary goods to obtain the same quantity of manufactured goods. The solution, according to Prebisch, was import substitution, through which tariffs are imposed on goods from industrialized countries so that a space can be created for domestic manufacturers to produce simple consumer goods.

Dependency theory took on a more radical direction in the hands of Paul Baran and Andre Gunder Frank. For Baran, dependency was characterized by a dual economy comprised of a large agriculture sector with extremely low productivity and a small industrial enclave that could not find a domestic market for its goods. Shifting Marx’s paradigm, Baran argued that a surplus was extracted from the peasantry and appropriated by landowners, moneylenders, merchants, and a mainly foreign capitalist class. These groupings had little interest in development and often functioned as a “comprador class,” siphoning off the surplus to foreign capital and gaining privileges as a result. The only solution was extensive state intervention to promote national development.

Frank agreed that the cause of underdevelopment was the extraction of a surplus by metropolitan countries. This, however, occurred primarily through trade itself, rather than through a dualistic structure of the economy. The trading relationship with the metropolis affected all sectors of society and led to the draining away of resources. There was no original state of underdevelopment from which such countries had to incubate; they were underdeveloped through coming into contact with the metropolitan powers. The route to development lay, therefore, in delinking from the world economy.

Not everyone, however, shared this pessimism about the dual-sector model in underdeveloped countries. For W. Arthur Lewis, who won the Nobel Prize in Economics in 1979, the dual-sector economy meant that the modern capitalist sector could draw on a relatively unlimited supply of labor from the more traditional sectors without having to raise wages significantly. This meant that it could expand until the absorption of surplus labor was complete. Adopting a pragmatic approach to the use of public and private enterprise in the modern sector, he argued that it could give a positive feedback to the traditional sector by, for example, creating markets for its commodities.

EXPORT INDUSTRIALIZATION AND OTHER APPROACHES
The demise of dependency theory coincided with the emergence of a number of newly industrializing countries, particularly the ‘Asian Tigers’ of South Korea, Singapore, Taiwan, and Hong Kong. By seeking a niche in the world economy and opening their economies to foreign investment, these nations appeared to overcome the obstacles to development through adopting an export industrialization program. As a result, contact with the global economy did not intensify underdevelopment, but instead allowed them to rapidly industrialize.

As the process of industrialization has spread, however, some older predictions are also being questioned.
According to Simon Kuznets’s famous hypothesis, economic inequality should increase during the early stages of industrialization because an income gap will grow between those in rural and urban areas. Over time, however, this inequality should decrease as mass education opens the possibility of a more meritocratic society. Yet while this may appear to have been the case up to the 1970s, there has been a return to growing levels of inequality since then. As outlined by Robert Pollin in *Contours of Descent* (2003), evidence from the United States indicates that the share of wealth held by the top 10 percent of the population has grown, and that the difference between the pay of the average CEO and that of the average employee has multiplied considerably.

**DEINDUSTRIALIZATION**

Current debates also focus on deindustrialization. According to Robert Rowthorn and Ramana Ramaswarmy, the share of employment in industry in the twenty-three most advanced countries declined from 28 percent of the workforce in 1970 to 18 percent in 1994. The growth in services and the development of a “knowledge society” has led many to argue that the transition to a postindustrial society has already occurred. However, this ignores the fact that modern societies continue to rely heavily on mass-produced goods, and it fails to explain how most foreign direct investment (FDI) is still going to the advanced industrial economies, rather than to those with an abundance of cheap labor. The rise in employment in services may, in fact, be the result of the relatively slower growth of labor productivity in that sector when compared to manufacturing. The process of industrialization, therefore, appears to still have a long way to go.

**INDUSTRY**

Industry refers to the organization of the economy around a particular set of products or related activities. For practical purposes, researchers may wish to compare the structures of different product or country markets either simultaneously or over a defined time period. To meet this need, government statistical agencies have developed standardized systems for classifying the activities of firms into industries. The NACE classification system, which is a French acronym for General Industrial Classification for Economic activities within European Communities, is used in the European Union, while in the United States, Canada, and Mexico, the North American Industry Classification System (NAICS, pronounced "nakes") is used. These systems broadly classify business establishments according to their primary activity.

Unlike standard microeconomic analysis, the study of industrial organization takes as its starting point the view that markets are less than perfect. "Actually existing capitalism" does not operate according to price competition alone, but promotes a variety of business strategies. These are affected by the way that markets for industries are “embedded” in a particular institutional climate. There are also barriers to entry in markets that can result in minimizing the full force of competition.
The study of industrial organization focuses on the link between market structure and business conduct in determining market performance. Market structure can vary from conditions of near full competition to oligopolies with high barriers to entry. A key feature of any particular market is the degree of concentration in a small number of firms. The level of concentration can be measured by a Lorenz curve that plots the cumulative percentage of market output against the cumulative percentage of firms from smallest to largest. The market structure can affect business conduct in terms of pricing, research and development, or branding strategies. Finally, this leads to measures of business performance in terms of dynamic or product efficiency, profitability, or growth. Writers from the early Harvard school placed primary emphasis on market structure, whereas those from the Chicago school have attempted to use traditional price theory in their analysis of industrial performance.

The historical pattern by which particular countries industrialized can also have an important influence on the structure of its industries. In Europe, for example, the reliance of Britain on the markets of its empire inclined firms toward labor-intensive, simple, and cheap products. This led to a weakness in manufacturing after World War II (1939–1945), and today Britain has one of the highest rates of deindustrialization in the world. By contrast, the late industrialization of Germany, combined with a close interaction with the banks, led to an emphasis on technological sophistication and cost containment, which led to greater success for German manufacturing.

Industrial development can also be affected by different modes of regulation, defined as complexes of institutions, norms, and regulating networks that affect the behavior of firms. Among these complexes are the structure of bargaining over the wage-effort contract, the institutional compromises at the level of the state, the relationship between industry and finance, and the international trade regime. The mode of regulation can evolve through sociopolitical conflict, which eventually has an impact on industry.

INEGALITARIANISM
There have been many defenses of inequality, several of which are rooted in moral or religious views (as in Hinduism) or in peculiar views of human nature (as in the teachings of Aristotle). Counter to such views, it is commonly presumed today that equality is preferable to inequality but that it should be balanced against other considerations that may causally trade off with it. Standard micro-level functional arguments in favor of inequality assert that inequality enhances production either because unequal incentives or unequal power (as in a hierarchy) are needed to organize the production of beneficial goods, both personal and collective, or because the productively efficient division of labor entails inequality.

These arguments generalize to macro-level claims about the organization of society. First, equality entails reduced incentives to those who are especially productive and leads to a trade-off between equality and the efficiency of production (Rawls 1971, Okun 1975). Second, hierarchy, and therefore inequality, is virtually necessary for achieving many desirable social goals. Finally, the division of labor is generally necessary in a modern society (Smith [1776] 1976; Durkheim [1893] 1933). At the societal level at least three further trade-offs undergird support for equality. First, the political power to achieve equality entails the power to do much else, including very undesirable things such as suppression of thought and dis-
sent. Second, equality in a single society requires autarky and risks the selective emigration of the especially productive; both of these effects are likely to be economically crippling. Finally, in many areas, those who have greater resources than others can be trailblazers who support innovations that eventually benefit almost everyone (Hayek 1960, p. 44).

Each of these relationships involves a trade-off of equality for something else: productivity, successful organization, lack of suppression, economic viability, or innovation. In each of these cases, although there might be disagreements about the scale of the trade-off of equality that a society should bear, there will probably be little disagreement that some trade-off is desirable or even necessary. Again, inequality in these arguments is functional in that it leads to greater production, prosperity, and liberty.

Gender inequality may have arisen from or been reinforced by the efficiency of a gendered division of labor, with women specialized in childbearing, childrearing, and other home-oriented activities while men specialized in fieldwork. Racial and ethnic inequality seem unlikely to have resulted from their overall efficiency. They must generally follow from normative spurning of an out-group or from taking advantage of the subordinate group by making them do subordinate jobs. The push for equality of these groups and women is commonly from normative claims for the equality of all. But equality for all typically only means that the subordinate groups’ members and women should face opportunities comparable to those of the rest of society, as unequal as those may generally be.

Major defenses of general social inequality in our time are functionally based in causal relations and have general significance beyond any idiosyncratic ethnic, gender, moral, or religious view. On these arguments there are reasons to think inequality either good or at least better than its implicit costs in an alternative.

Each of the arguments in favor of inequality in society might have a counterpart at the level of small groups or organizations; indeed, they are all expressed through actions at the micro level. However, relatively little attention has been paid to some of these effects at the micro level. The issues are especially important in macro contexts of developing economies and in micro contexts of differential power of the groups, such as those defined by gender and ethnicity, to which individuals belong and through which they are commonly identified.

Notions of inequality play a significant role in pragmatic political debates about democracy. James Madison (1751–1836), leader of the Constitutional Convention of 1787, and many others writing at the time of the drafting and adoption of the U.S. Constitution were deeply worried that democracy would lead to the expropriation of property. Given the vote, the large majority who were relatively poor in comparison to Madison, Thomas Jefferson (1743–1826), George Washington (1732–1799), and other holders of grand estates might choose to levy heavy taxes on property and block its simple inheritance. Or they might simply seize property. This is what happened in many socialist nations, except that the appropriation was done by dictatorial, not democratic governments. It is perhaps ironic that liberal democracy is now thought to be a safeguard of property and is therefore associated with substantial inequality of wealth. The central difference between the liberal democracies and the socialist autocracies is that the former have relatively weak governments while the latter have very strong governments. While a strong government does not guarantees egalitarian policies, a weak government probably does lead to inegalitarian outcomes. But, again, a potential cost of the strong government that is necessary for egalitarianism is the capacity to intervene in lives in many ways other than merely economically.

INEQUALITY, GENDER
In the 1968 International Encyclopedia of Social Sciences, there is no entry for gender inequality. In 2006, thirty-eight years later, Carolyn Hannon, director of the United Nations Department of Economic and Social Affairs, Division for the Advancement of Women, stated: “It is difficult to say with certainty what a world truly based on gender equality would look like, since we are still so far from achieving it” (2006, p.1). This statement shows how awareness of gender as an analytical category and gender inequality as a lived phenomenon has grown since the late
1960s. The world is deeply divided and organized by gender, defined as a set of socially constructed practices linked to biological sex that shape how individuals understand the categories of woman and man. Gender as a process is historically and culturally specific; manifestations of women's subordination are highly varied yet intricately connected. Not only does the form and extent of women's oppression vary from country to country, but it is also always shaped by relations of power based on race, class, ability and sexual orientation. Gender inequality is recognized as a persistent and detrimental aspect of all human societies.

While there is debate about the origins of gender inequality, the material effects of it are easily identifiable. According to the Women's Environment and Development Organization, "Women work two-thirds of the world's working hours. They also produce half of the world's food. However, women earn only ten percent of the world's income, and own less than one percent of the world's property" (2005, p.1). Poverty itself has been feminized: approximately 70 percent of the people living on less than one dollar a day are women or girls. The differential treatment of men and women is evident in material conditions and supported by ideological practices. Men are numerically dominant in key global and national decision-making positions such as international organizations, governments, and boards of directors of private enterprise. Men, therefore, greatly control access to resources and are the key architects of social, economic, and political policies. Gender inequality requires the daily exercise of power to be maintained. Further, the work of men is more highly paid and is accorded greater status than the work of women, which is often unpaid and not recognized as work. Joni Seager and Ann Olson in Women in the World: An International Atlas note, "Everywhere women are worse off than men: women have less power, less autonomy, more work, less money, and more responsibility. Women everywhere have a smaller share of the pie; if the pie is very small (as in poor countries), women's share is smaller still. Women in rich countries have a higher standard of living than do women in poor countries, but nowhere are women equal to men" (1986, p. 7).

In most regions of the world, gender relations were transformed in the twentieth century by the globalization of economies, technological developments, changes in how work is organized, warfare, and organized resistance movements (feminist, anticolonial, and civil rights). In the year 1900, the vast majority of women in the world had no formal legal rights, had extremely limited employment options, and were starting to gain access to higher education. Although the specificity of gender inequality in the global North (the world's wealthier nations, located predominantly in the northern hemisphere) and the South (the world's poorer nations largely of the southern hemisphere) may differ, women across the globe have worked together to effect systemic, lasting changes to improve the material conditions of women's lives. To be able to build an effective feminist movement, Chandra Mohanty has argued that women must work from a framework that highlights "mutuality, accountability and the recognition of common interests as the basis for relationships among diverse communities" (2003, p. 7). The notion of common interests between women of the South and North is important because it disrupts the construction of women of the North as liberated and women of the South as victims in need of rescue.

**ISSUES OF GENDER INEQUALITY IN WORK**

To understand gender issues and work, it is important to note that work has been largely conceptualized in the social sciences as activities performed for wages outside of the home, in the productive or public sphere. This is the work that men predominantly perform. Work done in the home by women—unwaged reproductive work that provides essential services for the functioning of the public sphere such as producing food for the family and childcare—is not considered to be part of the economy and has been rendered invisible in global accounting systems. According to Marilyn Waring in Counting for Nothing: What Men Value and What Women are Worth (1999), economic indicators such as the gross domestic product (GDP) and gross national product (GNP) do not include "activities that lie outside the production boundary—that is, in every notion, the great bulk of labour performed by women in an unpaid capacity" (p. 58). Since GDP and GNP are used to set policy priorities and measure the economic performance of a nation, the omission of women's work has far-reaching consequences. Women's contributions are not included in the calculation of major economic indicators thus rendering women's work invisible and naturalizing the belief that women do not contribute to the economy. Waring argued that the recognition of the unpaid work of women would necessarily lead to changes in social policy.

Women and girls perform the vast majority of work done in the home. This work is unpaid, devalued, and unrecognized as legitimate work and the sharp gendered division of labor is often justified by the argument that the activities of housework are a natural extension of women's biology. In Japan, for example, women reported that they spent twenty-nine hours per week doing housework; the average for men was only four hours. A survey conducted in India in 1999 found that women cooked for fifteen hours a week, had five minutes per day for leisure, slept two hours less per night than men, and spent ten times longer on household work than men. Men indicated that
they cooked for less than one hour per week and had, on average, two hours per day of leisure time (Seager, 2003, p. 70). In households where both partners work outside the home for wages, the division of labor within the home is disproportionately performed by women.

Entry into the waged labor market has been seen as a route to greater autonomy for women and since the 1970s the participation of women in the labor market has increased dramatically. In most countries, women now form at least 40 percent of waged workers. In 1999, 83 percent of women in Burundi, Mozambique, and Rwanda worked for wages. However, it is critical to examine the working conditions, wages, and occupational segregation faced by women. Women form approximately 75 percent of the world’s part-time workforce and are often employed on short temporary contracts without health benefits, job security, or protection against job-related health problems.

Women tend to be clustered in occupations in the service sector, in nurturing roles such as teaching and nursing as well as industrial assembly work on the global assembly line. These occupations receive lower levels of pay and social status. Even for identical work performed by women and men, work is valued differently depending on who performs the work. For example, in the United States in 1998, compared to the earnings of white men for the same work, white women earned seventy-three cents on the dollar, African American women earned sixty-three cents, and Hispanic American women earned fifty-three cents. The gender gap in earnings also varies by race. Even when women have the education and experience, they are often not able to break into the highest levels of management. According to Seager, in Canada and the United States in 1999, only thirteen of the largest one thousand corporations had women chief executive officers and only 4 percent of the senior management positions were filled by women.

**FORMAL RIGHTS AND POLITICAL POWER**

Women have made significant progress with respect to formal legal rights since the mid-nineteenth century. There has been a growing awareness of gender inequality in formal power and legal systems. Across the globe, women have fought for rights to make their status equal to that of men in areas of universal suffrage, property rights, and access to education. As of 2006, there is only one country, Kuwait, in which women do not have the same voting rights as men. Although the struggle for universal suffrage began in the mid-nineteenth century in many countries, the extension of voting rights was unevenly applied over a period of years to different groups of women. For example, in Canada, white women were first granted the right to vote in federal elections in 1918 yet it was not until 1960 that everyone in Canada regardless of gender or race was allowed to vote.

The extension of voting rights to women has not significantly changed the face of political representation and the exercise of political power. As of 2006 there is no country where women comprise 50 percent of elected representatives in government. In 1990 when women held, on average, 12 percent of all seats in national houses of parliament, the United Nations Economic and Social Council recommended that nations should aim to achieve a level of 30 percent representation by women by 1995. As of 2005 women’s political participation as a global average increased to 16 percent; only 19 countries met or exceeded the 30 percent target, according to the United Nations Statistical Division. The votes that women fought so hard for do not seem to have translated into direct political power for women as a group. Gender inequality is also prevalent in religious institutions. In all mainstream religious traditions (Christianity, Islam, Judaism, Hinduism, Buddhism) women are either forbidden from participating in leadership roles or sharply limited in what roles they can assume.

Feminists have argued that women and men are born with equal human capacity to learn, develop, and contribute to shaping the world. It is through the social organization of gender and gender roles that limit the potential of women to contribute to their full ability. Since 1960 there have been many positive developments, such as increased participation of women in political leadership roles and increased access for women and girls to education. One significant indicator of the success of feminist organizing is how an awareness of gender inequality as manifested in violence against women and reproductive health issues has been moved to the center of national and global discussions. Gender inequality has become a key focus of the United Nations. In 1975, the first World Conference on Women was held in Mexico with 133 governments participating in the discussions. Since 1975 there have been four additional conferences (Copenhagen, 1980; Nairobi, 1985; Beijing, 1995; New York, 2005) with participation increasing with each meeting. In 1995 more than 47,000 women and men participated in the creation of the Beijing Declaration and the Platform for Action. The Platform clearly stated that the empowerment of women and gender equality were critical to international development, peace, and human rights. One hundred eighty-nine countries endorsed the Platform, giving gender inequality a new profile in the formation of national policies and legislation.

Equality between women and men will not be achieved only by the implementation of legal reforms that position men and women as the same; there remains much work to be done beyond the achievement of formal
legal rights. The elimination of global gender inequality will require a fundamental transformation of social relations between women and men.

INEQUALITY, INCOME

Income inequality is an important aspect of the economic and social well-being of a nation. The axiom “the rich are getting richer and the poor are getting poorer” is synonymous with rising income and wealth inequality. Both affluent and poor countries experience some degree of income inequality.

Income inequality rose in the United States between the mid-1970s and early-2000s based on several measures. The United States generally exhibited the highest degree of income inequality of the industrialized OECD (Organization for Economic Cooperation and Development) countries, although research by Peter Gottschalk and Timothy Smeeding (2000) did not discern any universal trend. According to opinion polls by Demos, a U.S. public policy organization, American public opinion toward income inequality tends to shift in response to media reports on excessive executive compensation, corporate downsizing, and the state of the U.S. economy.

Opinions are divided on whether society should be concerned about income inequality. Economists Martin Feldstein and Anne Krueger argue that policymakers should focus on reducing poverty, not inequality. This is because an increase in inequality will occur even though all income-receiving units (IRUs) are better off in absolute terms if the incomes of richer IRUs rise by higher proportions than those of their poorer counterparts. An alternative view, articulated by Simon Kuznets (1901–1985) and Kenneth Arrow, winners of the 1971 and 1972 Nobel Prize in Economics, respectively, is that income inequality is an important determinant of aggregate savings and growth, and the perception of unfairness it entails may cause political instability and social conflict.

MEASURING INCOME INEQUALITY

One way of analyzing income inequality trends is to examine the income shares accruing to some segment of the population (e.g., the poorest and richest 10 percent). A falling (rising) income share of the poorest (richest) group indicates rising inequality.

A summary inequality measure is a single number computed from the incomes of several IRUs (individuals, households). This number summarizes the degree of income inequality, with higher values indicating greater inequality.

The Gini index or Gini coefficient—named after Corrado Gini (1884–1965), the Italian statistician who developed it in 1912—is a popular summary measure. It ranges from zero for perfect equality (all IRUs receive identical incomes) to one for perfect inequality (one IRU receives all the income). For example, the World Bank (2005) reports the 2000 Gini index for the United States and Canada as 0.38 and 0.33, respectively, indicating that the United States had greater inequality. Such international comparisons are strictly valid if they are based on common definitions of IRUs and income (gross income, net income) and similar geographical coverage (national, urban).

Frank Cowell (1995) provides details (including formulas) of the Gini index and other summary measures. Cowell describes the generalized entropy (GE) family, which includes the mean logarithmic deviation (GE(0)), Theil’s index (GE(1)), and half the squared coefficient of variation (GE(2)) as special cases, and Atkinson’s measure.
Atkinson’s measure ranges from zero to one and GE from zero to infinity.

There is no single best summary inequality measure. The choice among summary measures is influenced by: (1) computational convenience; (2) satisfaction of desirable properties, including scale independence (multiplying all incomes by a constant should not affect inequality), the Pigou-Dalton transfer principle (an income transfer from a richer to poorer IRU that does not reverse their ranking should reduce inequality), anonymity/symmetry (identities of IRUs are irrelevant), population independence (doubling population size by replicating every IRU should not affect inequality), and decomposability (total inequality should be conveniently broken down by population subgroups or income components); and (3) the portion of the income distribution to emphasize.

The availability of software for computing inequality measures has rendered computational considerations less important. The Gini index, GE, and Atkinson’s measure satisfy scale independence, the transfer principle, anonymity/symmetry, and population independence. The Gini index cannot be conveniently decomposed and is more sensitive to income changes in the middle of the distribution. The sensitivity problem is circumvented by computing a generalized/extended Gini, whose formula, like that of Atkinson’s measure and GE, incorporates an inequality aversion parameter that can be changed to stress different portions of the income distribution. The GE is renowned for its additive decomposability (total inequality in a population that is partitioned according to race, gender, or other characteristics is the sum of within-group inequality and between-group inequality).

The degree of income inequality can also be deduced graphically from a Lorenz curve. When comparing non-crossing Lorenz curves, the one with greater curvature away from the perfect equality line indicates greater inequality. The Gini index is twice the area between the Lorenz curve and the perfect equality line, which may be inaccurate if the Lorenz curve is constructed from data that are grouped into income brackets, as statistical agencies often do.

INCOME INEQUALITY WITHIN AMERICAN SOCIETY AND OTHER OECD COUNTRIES

The Gini index for U.S. household income inequality, reported by the U.S. Census Bureau, increased from 0.397 in 1975 to 0.466 in 2001. Both the GE and Atkinson’s measure also increased during this period, indicating rising inequality.

Two factors complicate the analysis of the observed inequality trends. First, the trend may depend on whether a narrow definition of income (market income) or a broader definition that takes into account taxes, social transfers (e.g., child benefits), and noncash benefits (e.g., food stamps) is considered. Rising social transfers may offset an increase in earnings inequality. Second, since summary measures are based on household surveys, researchers should test whether observed inequality changes are statistically significant by computing an appropriate standard error. Until the mid-1990s, many practitioners eschewed this issue because of the complexities of most standard error formulas. Advances in computing have facilitated significance tests for inequality changes using the bootstrap standard error, as Martin Biewen (2002) has demonstrated.

Economic historian Peter Lindert (2000) has summarized the vast literature explaining the rise in U.S. income inequality. The rise is ascribed to a complex mix of economic and social/demographic factors. Since earnings constitute the largest component of income for most IRUs, explanations of rising inequality in the United States have focused mainly on earnings inequality. They include the weakening of unions, technological changes requiring highly skilled workers, outsourcing of jobs, and immigration. Other explanations include import competition from low-cost countries, government tax and income transfer policies, and the rise in single-parent families. Similar factors have been used to explain inequality trends in other industrialized OECD countries, with variations in the relative importance of the factors.

ECONOMIC GROWTH AND INCOME INEQUALITY

Does economic growth lead to rising inequality? In 1955 Kuznets postulated the existence of an inverted U-curve relationship between economic growth and income inequality by tracking the historical experiences of England, Germany, and the United States. This U-curve hypothesis contends that the intersectoral shifts associated with the early stages of economic growth exacerbate inequality (the rising portion of the inverted U-curve). At some threshold level, inequality peaks and then falls (the falling portion of the inverted U-curve).

The vast literature on the U-curve hypothesis, reviewed by economist Ravi Kanbur (2000), reveals mixed empirical results. Furthermore, government policy is important in influencing the direction of inequality. Regarding the reverse causation from income inequality to economic growth, empirical evidence by Klaus Deininger and Lyn Squire (1998) reveals that inequality in land distribution is a more important determinant of future growth than income inequality.
INCOME INEQUALITY, RACE, ETHNICITY, WEALTH INEQUALITY, AND INTERGENERATIONAL MOBILITY

It is now widely recognized (e.g., World Bank 2005) that the root cause of persistent earnings and income inequality is unequal opportunities. For example, sustained discrimination in employment or education against a particular racial or ethnic minority group could result in persistently low earnings for the group’s members, resulting in an inequality trap.

The link between ethnicity and income inequality is convoluted. Economists William Darity and Ashwini Deshpande (2000) articulate how overall inequality could drive interethnic inequality and vice versa. Shelly Lundberg and Richard Startz (1998) explain how community influence and loyalty could shape interethnic inequality even without discrimination. Some have argued that ethnically homogeneous societies should have less inequality since assimilation by ethnic groups is easier and support for income redistribution is more likely. Fractionalization indexes, which measure the probabilities that two randomly selected individuals from a population belong to different ethnic, linguistic, or religious groups, have been used in empirical investigations of the ethnic-diversity income inequality nexus, with mixed results.

The causality between wealth inequality and income inequality may potentially run two ways. On the one hand, those with greater wealth accumulation are more likely to invest and generate higher incomes. On the other hand, those with higher incomes have higher potential to accumulate more wealth.

Are the children of poor parents destined to remain poor? This is the issue of intergenerational mobility, the relationship between a person’s socioeconomic status and that of his or her parents. The rich are capable of providing their offspring with a better education, increasing their chances of earning higher incomes. Also, the offspring of the rich are likely to inherit greater wealth, which aids the wealth accumulation process for the next generation. Thomas Piketty (2000) has surveyed theoretical and empirical literature on intergenerational mobility. Economists and sociologists measure the degree of intergenerational mobility by computing an intergenerational elasticity in income and wealth. Unfortunately, intergenerational elasticity estimates are sensitive to the methodology employed. Irrespective of the exact magnitude, there is no doubt that the level of opportunities allowed by society determines intergenerational mobility.

INEQUALITY, POLITICAL

Of the disparities among ordinary people in whatever is scarce and valued in a society—economic wherewithal, social respect, public influence, health, freedom—political equality is relevant most especially in democracies. In contrast to authoritarian systems, democracies are based on the expectation that the people are sovereign and that public officials are to be equally accessible and accountable to all. In spite of the egalitarian commitment embodied in the principle of one person, one vote, political equality among ordinary people is not the same thing as equal political power, even in democracies. Those who, by dint of election or appointment, are entrusted with the responsibility for governing—from the prime minister to the city council member—inevitably wield greater political power than others. Instead of equal power, therefore,
political equality among citizens would seem to require that they enjoy equal political rights, equal political voice, and equal political responsiveness.

POLITICAL RIGHTS
There is no possibility of political equality without certain rights. The rights intrinsic to what T. H. Marshall calls “civil citizenship” and “political citizenship” provide an essential foundation for political equality (Marshall 1964, chapter IV). Included within civil citizenship are due process of law, with the concomitant right to assert and defend oneself on terms of equality in the courts, and the right to think, speak, and worship freely. Under the umbrella of political citizenship is the right to share in political power, either by acting as a political decision maker or by influencing the choice of such decision makers by voting and otherwise taking part in the processes by which they are chosen. Such rights are not universally shared even in what can be considered to be functioning democracies. Historically, women were everywhere denied the rights necessary for political equality, as were other groups in particular places—for example, African Americans in the American South during the Jim Crow era or native blacks in South Africa during apartheid. Although there are variations across countries, all contemporary democracies abridge the political rights of children and resident aliens. Some add felons and the mentally incompetent to the list.

POLITICAL VOICE
A second requirement for the achievement of political equality is equality of political voice. Political voice refers to the sum total of political inputs that citizens in a democracy use to control who will hold political office and to influence what public officials do. Through their political voice, citizens raise political issues, communicate information about their political interests and concerns, and generate pressure on policymakers to respond to what they hear. Equal political voice requires not that all individuals are equally active, but that aggregate participatory input is representative across all politically relevant groups and categories.

Although the particular mix will vary from polity to polity, citizens in a democracy have a variety of options for the exercise of political voice. They can seek indirect influence through the electoral system by voting or engaging in other efforts to support favored political parties or candidates, or they can seek direct influence through the messages they send to office holders about their politically relevant preferences and needs. They can act individually or collectively. They can undertake mainstream activities, such as joining organizations or contacting public officials, or challenging ones, such as attending protests or demonstrations. Achieving equality in political voice is much more difficult than achieving equality of political rights. Individual citizens differ in their capacity and desire to take part in politics, and political activities differ in the extent to which the demanded inputs—time, money, or skills—are conducive to broad and representative participation, on the one hand, or to participation by narrower and less representative publics, on the other. In all systems, political voice is skewed, at least to some degree, in the direction of those with high levels of income, occupational status, and especially education. What this implies is that public officials hear an unrepresentative set of messages: They receive disproportionate information about the interests and opinions of, and feel more constrained to respond to, the affluent and well-educated. The extent to which unequal political voice is structured by occupation, education, and income implies, moreover, that disadvantaged groups defined along axes other than social class are also underrepresented politically. In most democracies, the political voice of women is muted, as is, in many polities, the political voice of racial, ethnic, or linguistic minorities. In many cases—for example, African Americans and Latinos in the United States—the inequality in political voice can be explained entirely in terms of socio-economic disadvantage without reference to a group-specific experience or identity. Nevertheless, whether the explanation for the inequality of political voice derives from socio-economic disparities or another aspect of collective experience, the bottom line is that policymakers hear less about the preferences, concerns, and needs of some individuals and some groups.

Although inequalities of political voice are biased in favor of the privileged in all democracies, many factors shape the extent of that socio-economic structuring. For one thing, the rules that govern politics can exacerbate or ameliorate inequalities of political voice. For example, where registration is difficult and electoral turnout is voluntary, as in the United States, the electorate tends to be less representative of the citizenry as a whole than in polities where registration is less demanding or, as in Belgium and Australia, turnout is compulsory. The rules governing campaign finance are also relevant. Free-for-all methods of financing campaigns and a major presence of corporate campaign contributions predispose a polity to inequalities of political voice. In addition, the nature of the institutions that link citizens to policymakers can have an impact on inequalities of political voice. High levels of membership in voluntary associations and the presence of both strong labor unions and a labor or social democratic party, as in the Nordic countries, tend to mute inequalities of political voice. Furthermore, government policies—ranging from free and compulsory education to progressive taxation to the provision of a social safety net—can reduce the socio-economic inequalities among individuals that are associated with inequalities of political voice.
POLITICAL RESPONSIVENESS

Political equality requires not just that citizens speak but that public officials listen. The most complex aspect of political equality, equality of political responsiveness is nearly impossible to measure and highly contested theoretically. Social scientists of a Marxian inclination, along with those who, like Charles E. Lindblom, posit the “privileged position of business,” conclude that formidable political resources and control of employment give the corporate sector—corporations and trade and other business associations—the upper hand in any public controversy (Lindblom 1977, chapter 13). That said, there are substantial obstacles to making a systematic empirical assessment of policymakers’ responsiveness to various competing forces. Especially since political influence is often exercised behind the scenes or used to shape the political agenda rather than the content of decisions, in any particular policy controversy it is difficult to discern who is exercising power and to whom decision makers are responding. Besides, in aggregating across issues, it is difficult to specify a universe of political controversies to serve as a baseline.

Furthermore, democratic theorists raise concerns about the universal desirability of equal responsiveness. Equal responsiveness in every political conflict would constitute a form of majoritarian democracy that would grant no space for the exercise of independent judgment by political leaders, who may command special information, experience, or insight. Furthermore, it would entail no deference to intensity of preference. That is, an indifferent majority would inevitably prevail over a minority that cares a lot. If such a political configuration were present over and over, that minority would never achieve its proportionate share of political influence. Moreover, if not coupled with equal voice, a pattern of equal responsiveness would give advantage to the noisy over the silent and produce a circumstance far from political equality.

INEQUALITY, RACIAL

Social inequality refers to “the condition whereby people have unequal access to valued resources, services, and positions in society” (Kerbo 1983, p. 250). Racial inequality in turn can be defined as the limited economic and social opportunities that are distributed along racial lines. Societies where racial inequalities are high are characterized by large disparities among different races and ethnicities in such areas as housing, education, employment, income, and health care. While some researchers argue that inequalities exist because of the efforts (or lack of efforts) of individuals, most contemporary scholars agree that persistent racial inequalities are a product of what Eduardo Bonilla-Silva (2001) refers to as a racialized social system—a system that reproduces and maintains the status of the dominant group socially, economically, politically, and psychologically. That is, racial inequality implies that access to resources and goods are overwhelmingly denied to people of color because of systemic rather than individual notions of racism. The social system upholds racism and maintains a racialized society.

THEORIES OF RACIAL INEQUALITY

Theories on racial inequality range from individual and cultural explanations that tend to lay blame on the victims (nonwhites) for their social and economic status in society to structural and systemic theories that tend to look beyond the individual to explain why most nonwhites, especially those with darker skin, continue to face discrimination in society. For example, deficiency theory, an outdated theory of racial inequality, argues that the economic, political, and social situation of some racial groups is due to some deficiency within the groups themselves. Deficiency theorists point to three causes for these deficiencies: biological, structural, and cultural. Regarding the first, scholars, the vast majority of whom were white, attempted to prove that the cause of racial inequalities stemmed from the biological inferiority of minority groups. Other researchers sought to demonstrate that there were basic flaws in the way minority groups struc-
tured their lives that helped to explain racial inequalities. Scholars also argued that racial and ethnic groups’ cultural traits and values served as a justification for the inequalities they experienced. The problem with deficiency theories, although still widely espoused by primarily conservative scholars, is their lack of empirical evidence and mostly unsubstantiated claims.

Other theories of racial inequality (e.g., bias theory) rely on the assumption that racial inequality is the result of individual prejudice and bias. The main criticism of such theories is that they ignore how societies are often structured along racial lines, which ultimately leads to social, residential, educational, and other forms of segregation. This theoretical framework ignores how racism can continue to operate in a society even when overt prejudices and discriminatory practices are no longer “socially” acceptable.

Structural theories of inequality identify racism within social structures, such as education, institutional policies, laws, and housing and health care practices. Many critical race theorists, such as Derrick Bell, Kimberlé Crenshaw, and Richard Delgado, have written about the importance of understanding why individual prejudices and biases do not fully explain the continuing existence of racism, especially given that many overtly racist policies and laws have long been dismantled. Structural theories tend to focus on how racism is maintained by identifying racist practices in institutions. For example, in the United States such practices as redlining and divestment in poorer neighborhoods result in lower property taxes. Since the quality of public schools is directly tied to property taxes, the schools in socioeconomically disadvantaged neighborhoods tend to have fewer resources compared to schools in more affluent neighborhoods. According to Douglas Massey and Nancy Denton (1993), the United States is a racially and residentially segregated society. African Americans are overrepresented in poor neighborhoods as a result of past and current racist housing practices, such as realtors refusing to sell or rent houses to African Americans in white neighborhoods. As a result African Americans continue to be steered into racially segregated neighborhoods where housing investment is low and social and economic opportunities are few or nonexistent.

Another theoretical framework examines the role of racial hierarchies to explain how different racial and ethnic groups fare compared to whites and to one another. One model, the black-white model, has generated major debate among scholars who study race and ethnicity. Joe R. Feagin (2000) and George Yancey (2006) argue that the black-white model is useful because African Americans are the most racially disadvantaged group and have experienced oppression far longer than most minority groups in the United States. Furthermore antiblack racism is one of the most ingrained social institutions in the United States (Feagin 2000). Researchers argue that this model can be applied to other racial and ethnic groups, but they maintain that the bipolar model is still necessary before one can fully understand racial inequality.

Critics of the black-white paradigm argue that it is outdated and does not take into account the demographic changes that have occurred in the United States as a result of increased immigration after the passage of the Immigration and Naturalization Act of 1965, which increased the number of immigrants of color to the United States. Further the black-white model allows only limited understanding of the racialization of nonwhite immigrant groups and their children because the model ignores the different factors associated with the process of racialization (e.g., religion, foreignness, language, citizenship, and gender). Immigrants vary in their experiences in the United States. For example, Asian Americans do not comprise one homogenous group but consist of individuals who come from different countries for a variety of reasons. Their experiences are not uniform but are diverse due to a broad range of factors, such as skin tone, class, reasons for immigrating, and religion, among others. Bonilla-Silva (2006) argues that Chinese Americans, for example, are often considered “honorary” whites, whereas Filipino Americans can be socioeconomically categorized as collective blacks. This is due to a variety of factors, such as skin tone and class status, that are not adequately addressed by the black-white model.

Racial Inequality in South Africa and Brazil

Racial inequality is not an American phenomenon; rather, it is international. South Africa is interesting because of the longevity of the legal system of racial segregation in this industrialized country. Apartheid was a postcolonial system of white supremacy that dominated South Africa. Under this system, all South Africans were racially categorized at birth as white, Asian, Colored, or black. Economic, political, and legal resources were distributed according to this racial categorization, with South African blacks receiving the fewest resources. Moreover blacks were not permitted to live where they wanted to, and they were forced to carry identification cards at all times, were prohibited from marrying outside of their race, and were denied citizenship in their own land. According to Gay Seidman (1999), South Africa turned toward apartheid rather than follow the pattern of European decolonization because South African blacks continued to provide a source of cheap labor to South African whites.

While the dismantling of apartheid in 1994 led to a concerted effort to democratize South Africa and produce
radical changes that would result in racial equality, this proved difficult to achieve because of the extent of racism that apartheid ingrained in the economic, social, and political structures. The dismantling of apartheid did not magically improve the situation for South African blacks. High rates of unemployment and substandard housing, education, and health care continue to plague them due to years of racial oppression and exploitation (Winant and Seidman 2001). The racial inequality that an oppressive and violent system like apartheid leaves behind requires a radical restructuring of social structures. While the post-apartheid South African government is committed to creating an equitable society, it has yet to commit to radical plans for change.

Brazil has also seen racial oppression and inequality due to the impact of colonization by Portugal. In the twentieth century Brazil prided itself on being a “racial democracy” with little racial prejudice. This ideological claim has been tested by many scholars, including Edward Telles and Peter Wade. Between 1890 and 1940 the black Brazilian population decreased from 66 percent of the total population to 34 percent (Paixão 2004). During this period, policies promoting the immigration to Brazil of white Europeans, along with the enactment of a strict penal code against black Brazilians, were implemented in order to rid Brazil of its native black population. In spite of (or perhaps as a result of) this whitening agenda, the Brazilian black population grew to 47 percent of the population between 1940 and 1980 (Paixão 2004). Between the late 1930s and the early 1940s a new ideology emerged in Brazil—a Brazilian national identity where mixed blood was encouraged rather than discouraged. Although this new way of thinking seemed to be a radical shift toward racial equality, it inevitably denied blacks their history and culture and ignored the racial inequality they experienced. Studies indicate that blacks in Brazil continue to face racial discrimination and that, compared to whites, they tend to be paid lower wages and experience higher rates of illiteracy and unemployment.

RACIAL INEQUALITY IN THE UNITED STATES

As in Brazil and South Africa, racial inequality in the United States stems from a long and complex history of racial oppression. The history of racism in the United States is similarly tied to economic exploitation achieved through racial violence and justified through the creation and maintenance of racial hierarchies. The colonization of the United States resulted in the genocide of Native Americans who occupied the land prior to European settlement. White capitalists violently forced African slaves to the Americas for the purpose of unwaged labor, resulting in the economic growth of the United States. Theories of the racial inferiority of nonwhites—specifically African slaves, Native Americans, and Mexicans but many others as well—were invented to justify their exploitation and the use of violence against them.

Although overt racist policies and laws (e.g., slavery, legal racial segregation) have been dismantled in the United States, their effects remain embedded in social institutions. Quality education is tied to property value, resulting in greater social, political, and economic opportunities for those who live in affluent neighborhoods. In contrast, the overrepresentation of African Americans in poor neighborhoods results in decreased opportunities for upward mobility. Scholars note that the great health disparities between African Americans and white Americans are due to disparities in access to good health care, medical insurance, and preventative care. Low-wage, low-skilled, part-time jobs that do not provide benefits are predominately filled by people of color in the United States, a situation that results in a class of working poor. Racial profiling, along with stricter sentencing for African Americans convicted of crimes, results in their overrepresentation in American prisons and consequently decreased opportunities upon their reentry into mainstream society. Racial inequality continues to exist in the United States because society has been structured around racial lines that provide advantages to whites. Racial inequality endures because it is at home in a “color-blind” society that is ingrained with racist practices that are mostly ignored.

INEQUALITY, WEALTH

Wealth represents a stock of accumulated assets; income represents a flow of current output. Families not only receive income over the course of a year but also save part of their income in the form of housing, time deposits, stocks, bonds, and the like. Such accumulated savings are referred to as wealth. The first part of this entry explains why wealth, like income, has an important bearing on well-being. The second part develops the concept of household wealth and discusses some of the problems inherent in its measurement; the third presents time trends in the inequality of wealth in the United States; and the fourth shows international comparisons of wealth inequality.

WEALTH AND WELL-BEING

Why are we interested in household wealth? Most studies use income as a measure of family well-being. Though certain forms of income are derived from wealth, such as interest from savings accounts and dividends from stocks, income and wealth are by no means identical. Many kinds of income, such as wages and salaries, are not derived from household wealth, and many forms of wealth, such as owner-occupied housing, produce no corresponding income flow.

Moreover family wealth by itself is also a source of well-being, independent of the direct financial income it provides. There are six reasons. First, some assets, such as owner-occupied housing and consumer durables such as automobiles, provide services directly to their owners. Such assets can substitute for money income in satisfying economic needs. Families with the same money income but differing amounts of housing and consumer durables will have different levels of welfare.

Second, wealth is a source of consumption, independent of the direct money income it provides. Many assets can be converted directly into cash and thus provide for immediate consumption needs.

Third, the availability of financial assets can provide liquidity to a family in times of economic stress (such as those occasioned by unemployment, sickness, or family breakup). In this sense wealth is a source of economic security for the family.

Fourth, as the work of Dalton Conley (1999) has shown, wealth is found to affect household behavior over and above income. In particular Conley found that it is necessary to control for wealth in order to understand racial inequality, including differences in school performance and enrollment in the United States.

Fifth, as Seymour Spilerman (2000) argued, wealth-generated income does not require the same trade-offs with leisure as earned income. There is no cost in the form of the foregone alternative use of time in the case of wealth. Moreover, unlike labor earnings, the income flow generated by wealth does not decline with illness or unemployment.

Sixth, large fortunes can be a source of economic and social power that is not directly captured in annual income. Large accumulations of financial and business assets can confer special privileges to their holders. Such large fortunes are often transmitted to succeeding generations, thus creating family “dynasties.” In these six ways wealth holdings provide another dimension to household welfare over and above income flows.

WHAT IS HOUSEHOLD WEALTH?

The conventional definition of household wealth includes assets and liabilities that have a current market value and that are directly or indirectly marketable. In the Survey of Consumer Finances conducted by the Federal Reserve Board of Washington, D.C., on a triennial basis, marketable wealth (or net worth) is defined as the current value of all marketable assets less the current value of debts. Total assets are the sum of (1) owner-occupied housing; (2) other real estate; (3) cash, demand and time deposits, certificates of deposit (CDs), and money market accounts; (4)
The figures in table 2 show that wealth inequality, after rising steeply between 1983 and 1989, remained virtually unchanged from 1989 to 2004. The share of wealth held by the top 5 percent rose by 2.8 percentage points from 1983 to 1989, that of the top quintile by 2.2 percentage points, and the Gini coefficient (an index that ranges from zero to one, where a higher number indicates greater inequality) increased from 0.80 to 0.83. Between 1989 and 2004 the share of the top 5 percent remained largely unchanged, and the share of the top quintile rose from financial securities; (5) the cash surrender value of life insurance; (6) pension accounts; (7) corporate stock and mutual funds; (8) unincorporated business equity; and (9) trust fund equity. Total liabilities are the sum of (1) mortgage debt and (2) consumer and other debt.

Table 1 presents the portfolio composition for the household sector in the United States in 2004 based on the Survey of Consumer Finances. Owner-occupied housing was the most important household asset, accounting for 33 percent of total assets. Land, rental property, and other real estate held by households made up 12 percent. Unincorporated business equity, which refers to small businesses (such as farms or stores) owned directly by individuals, comprised another 17 percent.

Liquid assets (cash, demand, time and savings deposits, money market funds, CDs, and the cash surrender value of life insurance) comprised 7 percent of total assets. Defined contribution pension accounts, such as individual retirement accounts (IRAs) and Keogh and 401(k) plans, constitute savings like savings accounts but are especially designed to allow workers to save for retirement by providing tax-deferred savings. Pension accounts made up almost 12 percent of household assets. Financial securities, including bonds, notes, and financial securities issued mainly by corporations and the government, are “promissory notes” by which the borrower agrees to pay back the lender a certain amount of money (the principal plus interest) at a certain date. In 2004 they amounted to only 2 percent of total assets.

The next component is corporate stock and mutual funds. A corporate stock certificate issued by a company represents ownership of a certain percentage of the company's assets. A mutual fund is a package provided by a financial entity, such as a bank, that includes a portfolio of stocks and other financial instruments, such as bonds. Its chief advantage is that it helps diversify the risk associated with individual stock (and bond) movements over time. In 2004 stocks and mutual funds amounted to almost 12 percent of total assets. Personal trusts refer to financial instruments held in a special legal arrangement called a trust fund. In a typical trust, the assets are managed by a specially named administrator, and the income earned from the assets is remitted to individual beneficiaries. Trust fund equity comprised only 3 percent of total assets.

On the liability side, the major form of household debt is home mortgages. A mortgage is a loan issued usually by a bank for a period of fifteen to thirty years that is used to finance the purchase of real property. In 2004 mortgage debt comprised 75 percent of total household debt. The remaining 25 percent consisted of other household debt, including automobile and other consumer loans and credit card debt. Total household debt amounted to 16 percent of the value of household assets.

A theme that regularly emerges in the literature on household wealth is that there is no unique concept or definition of wealth that is satisfactory for all purposes. One concept that is broader than marketable wealth is the sum of marketable wealth and consumer durables. Consumer durables, such as automobiles, televisions, and furniture, provide consumption services directly to the household and as such function like “annuities.” However, since they are not easily marketed and their resale value typically far understates the value of their consumption services, they are often excluded from marketable wealth. A still broader definition of wealth includes the value of future social security benefits the family may receive upon retirement (social security wealth) as well as the value of retirement benefits from private pension plans (pension wealth). However, even though these funds are a source of future income to families, they are not in the family's direct control and cannot be marketed and are also excluded from marketable wealth.

### WEALTH INEQUALITY TRENDS IN THE UNITED STATES

The figures in table 2 show that wealth inequality, after rising steeply between 1983 and 1989, remained virtually unchanged from 1989 to 2004. The share of wealth held by the top 5 percent rose by 2.8 percentage points from 1983 to 1989, that of the top quintile by 2.2 percentage points, and the Gini coefficient (an index that ranges from zero to one, where a higher number indicates greater inequality) increased from 0.80 to 0.83. Between 1989 and 2004 the share of the top 5 percent remained largely unchanged, and the share of the top quintile rose from...
83.5 to 84.7 percent. Overall the Gini coefficient fell very slightly, from 0.832 in 1989 to 0.829 in 2004.

The top 5 percent of families (as ranked by income) earned 32 percent of total household income in 2003, and the top 20 percent accounted for 58 percent—large figures but lower than the corresponding wealth shares. The time trend for income inequality was similar to that of wealth inequality. Income inequality increased sharply between 1982 and 1988, with the Gini coefficient rising from 0.48 to 0.52 and the share of the top 5 percent from 26.1 to 30.0 percent. There was then a further but smaller increase of the Gini index by 0.019 points from 1988 to 2003 and of the shares of the top 5 and 20 percent (see Wolff 1998, 2002, 2006 for further details).

**Table 3. The Size Distribution of Wealth in Selected Organization for Economic Cooperation and Development Countries, 1983–2001**

INTERNATIONAL COMPARISONS OF WEALTH INEQUALITY

Wealth inequality is also much higher in the United States than in the other four countries shown in table 3. The Gini coefficient for wealth in the United States in 1998 was 0.82, compared to 0.73 in Canada in 1999, 0.64 in Germany in 1998, 0.61 in Italy in 2000, and 0.52 in Finland in 1998. Similar disparities exist with regard to the share of top wealth holders. In the United States the top 10 percent held 71 percent of all wealth in 1998, compared to a share of 56 percent in Canada in 1999, 42 percent in Germany in 1998, and 49 percent in Italy in 2000. By 2000 or so Finland was by far the most equal of the five countries with comparable data, followed by Italy, Germany, Canada, and then the United States (see Wolff 1987, 1996 for earlier comparisons).

It is also of interest that wealth inequality rose in the United States, Canada, Italy, and Finland, while it declined sharply in Germany. The Gini coefficient rose by 0.027 in the United States between 1983 and 2001, by 0.036 in Canada from 1984 to 1999, and by 0.060 in Italy between 1989 and 2000. In Germany, in contrast, it plummeted by 0.108 from 1973 to 1998 (and by 0.061 from 1983 to 1998).

INFANT INDUSTRY

Governments in both developed and developing nations regularly apply the concept of infant industry to justify protective industrial and trade policy measures. The idea is that temporary support for a new branch of industry (for example, electronics, car manufacturing, or biotechnology) might be needed to help industry to grow and flourish, especially when efficient scales of production and technological skills have not yet been developed. If a young industry were exposed to foreign competition at an early stage, it is argued, it would not be able to survive. Temporary government protection in the form of subsidies, tariffs, or important quotas, then, allows an infant industry to “grow up.”

Although Alexander Hamilton (1755–1804), the first secretary of the treasury of the United States, followed this line of reasoning in his Report on the Subject of Manufactures (1791), the infant-industry argument is usually attributed to the German economist Friedrich List (1789–1846). In The National System of Political Economy ([1841] 1856, p. 378), List argued that the transition of a country’s economy from the agricultural to the industrial stage would not occur through the “natural course of things.” He recommended, therefore, that the government protect nation-specific manufacturing activities if some countries “outdistanced others in manufactures” (List [1841] 1856, p. 394). List stressed that this promotion of infant industries should build on unique national resources. Moreover, the protection should be temporary; it should stop as the infant industry matures.

International and development economists have related List’s infant-industry argument to the theory of comparative advantage. According to this view, countries should concentrate on those economic sectors in which they can produce more efficiently and cheaply than their trading partners. In theoretical terms, infant-industry pro-
tection is only legitimized until a potential comparative-advantage sector has become an actual comparative-advantage sector. Thus stated, the infant-industry argument does not conflict with the principle of comparative cost advantage. Economists have also identified other cases in which infant industries might need temporary protection. Countries that lack well-functioning capital-market institutions, such as banks and stock markets, usually have a shortage of venture capital that new industries urgently need to invest and grow. In such a case of market failure, supporting a sector in its early growth phase is justified. Moreover, whenever new industries generate social benefits for which they are not compensated (for example, a biotechnology sector contributing to the improvement of national health care), a government may reward them by offering temporary protection from foreign competition.

In all these cases, an industry should receive public assistance only if it meets two theoretical conditions. The first is that the sector must eventually be able to compete on its own. The second is that the ultimate gains of infant-industry protection for society must be large enough to compensate for the costs incurred during the period of government support. In practice, it is almost impossible to make a proper cost-benefit analysis, which explains why governments generally refer to the infant-industry argument on political rather than theoretical grounds.

**MIXED RESULTS**

Over the years, the infant-industry argument has persuaded many policymakers all over the globe. Indeed, the argument seems plausible and is theoretically valid under the right set of circumstances. The empirical evidence on the effectiveness of infant-industry protection is inconclusive, however; both developed and developing nations show mixed results. On the one hand, the economic history of some advanced countries suggests that protecting young industries was conducive for industrial development. The United States and Germany, for example, enjoyed high tariffs on manufacturing in the nineteenth century, while Japan benefited from import quotas until the 1970s. On the other hand, there are many examples of industries in North America and Europe (for example, the U.S. computer industry and the Swedish automobile industry) that were infants at one stage but grew and flourished without any government protection. During the 1950s and 1960s, infant-industry promotion in Latin America and Africa often took the form of import substitution, or the replacement of imported goods by products from domestic industries. In countries such as Mexico and Brazil the results of this inward-looking strategy to promote local industrial development were disappointing. In contrast, young industries in East Asian countries such as Taiwan and South Korea benefited from temporary protection, most likely because these sectors were oriented toward exports. The degree to which a country’s economic performance is due to such infant-industry strategies, however, is a matter of ongoing academic debate.

Despite its appeal to common sense, the infant-industry argument is often criticized. The crucial problem is how a government can determine in advance which industries have a potential comparative advantage for the country. In assessing opportunities for industrial growth, the state usually is no better informed than the market. In other words, it is hard for policymakers to “pick winners.” Moreover, if a government selects the wrong sector to protect, the costs to society are significant: The infant industry will use the support to expand its capacity but will require continued protection for its survival because no real comparative advantage can be developed. Instead of growing up, the industry will keep producing inefficiently and will become dependent on state assistance. In this case, a policy change is difficult since the infant industry has a vested interest and will fight to stay protected. Telling examples of protective strategies that turned out to be policies of “backing losers” are the British policy toward car manufacturing in the 1970s and the promotion of French microelectronics during the 1980s. In both cases sound economic reasons to stop protection were overridden by political desires to keep the “national champions” alive. Another problem with the infant-industry argument as applied by policymakers follows from historical evidence that countries tend to support similar growth industries during a given period of time. Since the end of the 1990s, for example, most advanced economies have treated their domestic information-technology sector as a growth industry. Hamilton and List, the pioneers of the infant-industry concept, already noted that such a bandwagon effect in industrial policy is inefficient from an economic perspective. After all, national comparative advantage comes from being different, not from doing the same as others do.

INFERENCE, BAYESIAN

Bayesian inference is a collection of statistical methods that are based on a formula devised by the English mathematician Thomas Bayes (1702–1761). Statistical inference is the procedure of drawing conclusions about a population or process based on a sample. Characteristics of a population are known as parameters. The distinctive aspect of Bayesian inference is that both parameters and sample data are treated as random quantities, while other approaches regard the parameters as nonrandom. An advantage of the Bayesian approach is that all inferences can be based on probability calculations, whereas non-Bayesian inference often involves subtleties and complexities. One disadvantage of the Bayesian approach is that it requires both a likelihood function that defines the random process that generates the data, and a prior probability distribution for the parameters. The prior distribution is usually based on a subjective choice, which has been a source of criticism of the Bayesian methodology. From the likelihood and the prior, Bayes’s formula gives a posterior distribution for the parameters, and all inferences are based on this.

BAYES’S FORMULA

There are two interpretations of the probability of an event A, denoted \( P(A) \): (1) the long-run proportion of times that the event A occurs upon repeated sampling; and (2) a subjective belief in how likely it is that the event A will occur. If A and B are two events, and \( P(B) > 0 \), then the conditional probability of A given B is \( P(AB) = P(AB)/P(B) \), where AB denotes the event that both A and B occur. The frequency interpretation of \( P(AB) \) is the long-run proportion of times that A occurs when we restrict attention to outcomes where B has occurred. The subjective probability interpretation is that \( P(AB) \) represents the updated belief of how likely it is that A will occur if we know B has occurred. The simplest version of Bayes’s formula is \( P(BA) = P(AB)/P(AB) = P(BA)/P(AB), \) where \( \sim B \) denotes the complementary event to B, that is, the event that B does not occur. Thus, starting with the conditional probabilities \( P(AB) \) and \( P(A|B) \), and the unconditional probability \( P(B) \) \( P(\sim B) = 1 - P(B) \) by the laws of probability, we can obtain \( P(BA) \). Most applications require a more advanced version of Bayes’s formula.

Consider the “experiment” of flipping a coin. The mathematical model for the coin flip applies to many other problems, such as survey sampling when the subjects are asked to give a “yes” or “no” response. Let \( \theta \) denote the probability of heads on a single flip, which we assume is the same for all flips. If we also assume that the flips are statistically independent given \( \theta \) (i.e., the outcome of one flip is not predictable from other flips), then the probability model for the process is determined by \( \theta \) and the number of flips. Note that \( \theta \) can be any number between 0 and 1. Let the random variable \( X \) be the number of heads in \( n \) flips. Then the probability that \( X \) takes a value \( k \) is given by

\[
P(X = k | \theta) = \binom{n}{k} \theta^k (1 - \theta)^{n-k}, \quad k = 0, 1, \ldots, n.
\]

\( \binom{n}{k} \) is a binomial coefficient whose exact form is not needed. This probability distribution is called the binomial distribution. We will denote \( P(X = k | \theta) \) by \( f(k | \theta) \), and when we substitute the observed number of heads for \( k \), it gives the likelihood function.

To complete the Bayesian model we specify a prior distribution for the unknown parameter \( \theta \). If we have no belief that one value of \( \theta \) is more likely than another, then a natural choice for the prior is the uniform distribution on the interval of numbers from 0 to 1. This distribution has a probability density function \( g(\theta) \) which is 1 for \( 0 \leq \theta \leq 1 \) and otherwise equals 0, which means that \( P(a \leq \theta \leq b) = b - a \) for \( 0 \leq a < b \leq 1 \).

The posterior density of \( \theta \) given \( X = x \) is given by a version of Bayes’s formula: \( h(\theta | x) = K(x)f(x | \theta)g(\theta) \), where \( K(x)^{-1} = \int f(x | \theta)g(\theta)d\theta \) is the area under the curve \( f(x | \theta)g(\theta) \) when \( x \) is fixed at the observed value.

A quarter was flipped \( n = 25 \) times and \( x = 12 \) heads were observed. The plot of the posterior density \( h(\theta | x) \) is shown in Figure 1. This represents our updated beliefs about \( \theta \) after observing twelve heads in twenty-five coin flips. For example, there is little chance that \( \theta \geq 0.8 \); in fact, \( P(\theta \geq 0.8 | X = 12) = 0.000135 \), whereas according to the prior distribution, \( P(\theta \geq 0.8) = 0.200000 \).

STATISTICAL INFERENCE

There are three general problems in statistical inference. The simplest is point estimation: What is our best guess for the true value of the unknown parameter \( \theta \)? One natural approach is to select the highest point of the posterior density, which is the posterior mode. In this example, the posterior mode is \( \hat{\theta}_{\text{Mode}} = x/n = 12/25 = 0.48 \). The poste-
Prior mode here is also the maximum likelihood estimate, which is the estimate most non-Bayesian statisticians would use for this problem. The maximum likelihood estimate would not be the same as the posterior mode if we had used a different prior. The generally preferred Bayesian point estimate is the posterior mean: \( \theta_{\text{MEAN}} = \int \theta \, b(\theta | x) \, d\theta = (x + 1)/(n + 2) = 13/27 = 0.4815 \), almost the same as \( \theta_{\text{Mode}} \) here.

The second general problem in statistical inference is interval estimation. We would like to find two numbers \( a < b \) such that \( P(a < \theta < b | X = 12) \) is large, say 0.95. Using a computer package one finds that \( P(0.30 < \theta < 0.67 | X = 12) = 0.950 \). The interval \( 0.30 < \theta < 0.67 \) is known as a 95 percent credibility interval. A non-Bayesian 95 percent confidence interval is \( 0.28 < \theta < 0.68 \), which is very similar, but the interpretation depends on the subtle notion of “confidence.”

The third general statistical inference problem is hypothesis testing: We wish to determine if the observed data support or lend doubt to a statement about the parameter. The Bayesian approach is to calculate the posterior probability that the hypothesis is true. Depending on the value of this posterior probability, we may conclude that the hypothesis is likely to be true, likely to be false, or the result is inconclusive. In our example, we may ask if the coin is biased against heads—that is, is \( \theta < 0.50? \) We find \( P(\theta < 0.50 | X = 12) = 0.58 \). This probability is not particularly large or small, so we conclude that there is not evidence for a bias for (or against) heads.

Certain problems can arise in Bayesian hypothesis testing. For example, it is natural to ask whether the coin is fair—that is, does \( \theta = 0.50? \) Because \( \theta \) is a continuous random variable, \( P(\theta = 0.50 | X = 12) = 0 \). One can perform an analysis using a prior that allows \( P(\theta = 0.50) > 0 \), but the conclusions will depend on the prior. A non-Bayesian approach would not reject the hypothesis \( \theta = 0.50 \) since there is no evidence against it (in fact, \( \theta = 0.50 \) is in the credible interval).

This coin flip example illustrates the fundamental aspects of Bayesian inference, and some of its pros and cons. Leonard J. Savage (1954) posited a simple set of axioms and argued that all statistical inferences should logically be Bayesian. However, most practical applications of statistics tend to be non-Bayesian. There has been more usage of Bayesian statistics since about 1990 because of increasing computing power and the development of algorithms for approximating posterior distributions.

TECHNICAL NOTES
All computations were performed with the R statistical package, which is available from the Comprehensive R Archive Network. The prior and posterior in the example belong to the family of beta distributions, and the R functions dbeta, pbeta, and qbeta were used in the calculations.

INFERENCE, STATISTICAL

To perform inference, in layman’s terms, is to make an educated or informed guess of an unknown quantity of interest given what is known. **Statistical inference**, again in layman’s terms, goes one step further, by making an informed guess about the error in our informed guess of the unknown quantity. To the layman, this may be difficult to grasp—if I don’t know the truth, how could I possibly know the error in my guess? Indeed, the exact error—that is, the difference between the truth and our guess—can never be known when inference is needed. But when our data set, or more generally, quantitative information, is collected through a probabilistic mechanism—or at least can be approximated or perceived as such—probabilistic calculations and statistical methods allow us to compute the probable error, formally known as the “standard error,” of our guess, or more generally, of our guessing method, the so-called “estimator.” Such calculations also allow us to compare different estimators, that is, different ways of making informed guesses, which sometimes can lead to the best possible guess, or the most efficient estimation, given a set of (often untestable) assumptions and optimality criteria.

Consider the following semihypothetical example. Mary, from a prestigious university in Europe, is being recruited as a statistics professor by a private U.S. university. Knowing that salaries at U.S. universities tend to be significantly higher than at European universities, Mary needs to figure out how much she should ask for without aiming too low or too high; either mistake could prevent her from receiving the best possible salary. This is a decision problem, because it depends on how much risk Mary is willing to take and many other factors that may or may not be quantifiable. The inference part comes in because, in order to make an informed decision, Mary needs to know something about the possible salary ranges at her new university.

**FROM SAMPLE TO POPULATION**

As with any statistical inference, Mary knows well that the first important step is to collect relevant data or information. There are publicly available data, such as the annual salary surveys conducted by the American Statistical Association. But these results are too broad for Mary’s purposes because the salary setup at Mary’s new university might be quite different from many of the universities surveyed. In other words, what Mary needs is a conditional inference, conditional on the specific characteristics that are most relevant to her goal. In Mary’s case, the most relevant specifics include (1) the salary range at her new university and (2) the salary for someone with experience and credentials similar to hers.

Unlike at public universities, salary figures for senior faculty at many private universities are kept confidential. Therefore, collecting data is not easy, but in this example, through various efforts Mary obtained $140,000, $142,000, and $153,000 as the salary figures for three of the university’s professors with statuses similar to Mary’s. Mary’s interest is not in this particular sample, but in inferring from this sample an underlying population of possible salaries that have been or could be offered to faculty members who can be viewed approximately as exchangeable with Mary in terms of a set of attributes that are (perceived to be) used for deciding salaries (e.g., research achievements, teaching credentials, years since PhD degree, etc.). This population is neither easy to define nor knowable to most individuals, and certainly not to Mary. Nevertheless, the sample Mary has, however small, tells her something about this population. The question is, what does it tell, and how can it be used in the most efficient way? These are among the core questions for statistical inference.

**DEFINING ESTIMAND**

But the first and foremost question is what quantity Mary wants to estimate. To put it differently, if Mary knew the entire distribution of the salaries, what features would she be interested in? Formulating such an inference objective, or estimand, is a critical step in any statistical inference, and often it is not as easy as it might first appear. Indeed, in Mary’s case it would depend on how “aggressive” she would want to be. Let’s say that she settles on the 95th percentile of the salary distribution; she believes that her credentials are sufficient for her to be in the top 5 percent of existing salary range, but it probably would not be an effective strategy to ask for a salary that exceeds everyone else’s.

Mary then needs to estimate the 95th percentile using the sample she has. The highest salary in the sample is $153,000, so it appears that any estimate for the 95th percentile should not exceed that limit if all we have is the data. This would indeed be the case if we adopt a pure nonparametric inference approach. The central goal of this approach is very laudable: Making as few assumptions as possible, let the data speak. Unfortunately, there is no free lunch—the less you pay, the less you get. The problem with this approach is that unless one has a sufficient amount of data, there is just not enough “volume” in the data to speak loudly enough so that one could hear useful messages. In the current case, without any other knowledge or making any assumptions, Mary would have no base to infer any figure higher than $153,000 to be a possible estimate for the 95th percentile.
MAKING ASSUMPTIONS

But as a professional statistician, Mary knows better. She knows that she needs to make some distributional assumptions before she can extract nontrivial information out of merely three numbers, and that in general, log-normal distribution is not a terrible assumption for salary figures. That is, histograms of the logarithm of salary figures tend to be shaped like a “bell curve,” also known as the Gaussian distribution. This is a tremendous amount of information, because it effectively reduces the “infinitely unknowable” distribution of possible salary figures to only two parameters, the mean and the variance of the log of the salary. Mary can estimate these two parameters using the sample mean of 11.884 and sample standard deviation of 0.048 provide valid estimates of the unknown true mean $\mu$ and true standard deviation $\sigma$. Because for the normal distribution $\mathcal{N}(\mu, \sigma^2)$ the 95th percentile is $z_{95} = \mu + 1.645\sigma$, Mary’s estimate for the 95th percentile for the log salary distribution is $11.884 + 1.645 \times 0.048 = 11.963$. Because the log transformation is strictly monotone, this means that Mary’s estimate for the 95th percentile for the salary distribution is $\exp(11.963) = \$156,843$, about 2.5 percent higher than the observed maximal salary of $\$153,000$!

ASSESSING UNCERTAINTY

With a sample size of three, Mary knows well that there is large uncertainty in estimating the mean $\mu$, as well as in estimating $\sigma$. But how do we even measure such error without knowing the true value? This is where the probabilistic calculation comes in, if the sample we have can be regarded as a probabilistic sample. By probabilistic sample, we mean that it is generated by a probabilistic mechanism, such as drawing a lottery. In Mary’s case, the sample was clearly not drawn randomly, so we need to make some assumptions. In general, in order for any statistical method to render a meaningful inference conclusion, the sample must be “representative” of the population of interest, or can be perceived as such, or can be corrected as such with the help of additional information. A common assumption to ensure such a “representativeness” is that our data form an independently and identically distributed (i.i.d.) sample of the population of interest. This assumption can be invalidated easily if, for instance, faculty members with higher salaries are less likely to disclose their salaries to Mary. This would be an example of selection bias, or more specifically, a nonresponse bias, a problem typical, rather than exceptional, in opinion polls and other surveys that are the backbone of many social science studies. But if Mary knew how a faculty’s response probability is related to the faculty member’s salary, then methods do exist for her to correct for such a bias.

Mary does not have such information, nor does she worry too much of the potential bias in her sample. To put it differently, she did her best to collect her data to be “representative,” being mindful of the “garbage-in—garbage-out” problem; no statistical analysis method could come to rescue if the data quality is just poor. So she is willing to accept the i.i.d. assumption, or rather, she does not have strong evidence to invalidate it. This is typical with small samples, where model diagnosis, or more generally, assumption checking is not directly feasible using the data alone. But contrary to common belief, just because one does not have enough data to check assumptions, this does not imply one should shy away from making parametric assumptions. Indeed, it is with small samples that the parametric assumptions become most valuable. What one does need to keep in mind when dealing with a small sample is that the inference will be particularly sensitive to the assumptions made, and therefore a sensitivity analysis—that is, checking how the analysis results vary with different assumptions—is particularly necessary.

Under the i.i.d. assumption, we can imagine many possible samples of three drawn randomly from the underlying salary population, and for each of these samples we can calculate the corresponding sample mean and sample standard deviation of the log salary. These sample means and sample standard deviations themselves will have their own distributions. Take the distribution of the sample mean as an example. Under the i.i.d. assumption, standard probability calculations show that the mean of this distribution retains the original mean $\mu$, but its variance is the original variance divided by the sample size $n$, $\sigma^2/n$. This makes good intuitive sense because averaging samples should not alter the mean, but should reduce the variability in approximating the true mean, and the degree of reduction should depend on the sample size: The more we average, the closer we are to the true mean, probabilistically speaking. Furthermore, thanks to the central limit theorem, one of the two most celebrated theorems in probability and statistics (the other is the law of large numbers, which justifies the usefulness of sample mean for estimating population mean, among many other things), often we can approximate the distribution of the sample mean by a normal distribution, even if the underlying distribution for the original data is not normal.

CONSTRUCTING CONFIDENCE INTERVALS

Consequently, we can assess the probable error in the sample mean, as an estimate of the true mean, because we can
use the sample standard deviation to estimate $\sigma$, which can then be used to form an obvious estimate of the standard error $\sigma/\sqrt{n}$. For Mary's data, this comes out to be $0.048/\sqrt{3} = 0.028$, which is our estimate of the probable error in our estimate of $\mu$, 11.884. In addition, we can use our distributional knowledge to form an interval estimate for $\mu$. Typically, an interval estimator is in an appealing and convenient form of "sample mean $\pm 2 \times $ standard error," which is a 95 percent confidence interval when (1) the distribution of the sample mean is approximately normal; and (2) the sample size, $n$, is large enough (how large is large enough would depend on problems at hand; in some simple cases, $n = 30$ could be adequate, and in others, even $n = 30,000$ might not be enough). For Mary's data, the assumption (1) holds under the assumption that the log salary is normal, but the assumption (2) clearly does not hold. However, there is an easy remedy, based on a more refined statistical theory. The convenient form still holds as long as one replaces the multiplier 2 by the 97.5th percentile of the $t$ distribution with degrees of freedom $n - 1$. For Mary's data, $n = 3$, so the multiplier is 4.303. Consequently, a 95 percent confidence interval for $\mu$ can be obtained as $11.884 \pm 4.303 \times 0.028 = (11.766, 12.004)$. Translating back to the original salary scale, this implies a 95 percent confidence interval ($128,541, 163,407$). This interval for the mean is noticeably wider than the original sample range ($140,000, 153,000$); this is not a paradox, but rather a reflection that with sample size of only three, there is a tremendous uncertainty in our estimates, particularly because of the long tail in the log-normal distribution.

So what is the meaning of this 95 percent confidence interval? Clearly it does not mean that $(11.766, 12.004)$ includes the unknown value $\mu$ with 95 percent probability; this interval either covers it or it does not. The 95 percent confidence refers to the fact that among all such intervals computed from all possible samples of the same size, 95 percent of them should cover the true unknown $\mu$, if all the assumptions we made to justify our probabilistic calculations are correct. This is much like when a surgeon quotes a 95 percent success chance for a pending operation; he is transferring the overall (past) success rate associated with this type of surgery—either in general, or by him—into confidence of success for the pending operation.

By the same token, we can construct a confidence interval for $\sigma$, and indeed for Mary's estimand, a confidence interval for the 95th percentile $z_{95} = \mu + 1.645\sigma$. These constructions are too involved for the current illustration, but if we ignore the error in estimating $\sigma$ (we shouldn't if this were a real problem), that is, by pretending $\sigma = 0.048$, then constructing a 95 percent confidence interval for $z_{95} = \mu + 1.65\sigma$ would be the same as for $\mu + 1.645 \times 0.048 = \mu + 0.079$, which is $(11.766 + 0.079, 12.004 + 0.079) = (11.845, 12.083)$. Translating back to the original salary scale, this implies that a 95 percent confidence interval for $z_{95}$ would be ($139,385, 176,839$). The right end point of this interval is about 15 percent higher than the maximal observed salary figure, $153,000$. As Mary's ultimate problem is making a decision, how she should use this knowledge goes beyond the inference analysis. The role of inference, however, is quite clear, because it provides quantitative information that has direct bearing on her decision. For example, Mary's asking salary could be substantially different knowing that the 95th percentile is below $153,000 or could go above $170,000.

**LIMITATIONS**

One central difficulty with statistical inference, which also makes the statistical profession necessary, is that there simply is no "correct" answer: There are infinitely many incorrect answers, a set of conceivable answers, and a few good answers, depending on how many assumptions one is willing to make. Typically, statistical results are only part of a scientific investigation or of decision making, and they should never be taken as "the answer" without carefully considering the assumptions made and the context to which they would be applied. In our example above, the statistical analysis provides Mary with a range of plausible salary figures, but what she actually asks for will depend on more than this analysis. More importantly, this analysis depends heavily on the assumption that the three salary figures are a random sample from the underlying salary distribution, which is assumed to be log-normal. Furthermore, this analysis completely ignored other information that Mary may have, such as the American Statistical Association's annual salary survey. Such information is too broad to be used directly for Mary's purposes (e.g., taking the 95th percentile from the annual survey), but nevertheless it should provide some ballpark figures for Mary to form a general prior impression of what she is going after. This can be done via Bayesian inference, which directly puts a probabilistic distribution on any unknown quantity that is needed for making inference, and then computes the posterior distribution of whatever we are interested in given the data. In Mary's case, this would lead to a distribution for $z_{95}$, from which she can directly assess the "aggressiveness" of each asking salary figure by measuring how likely it exceeds the actual 95th percentile. For illustration of this more flexible method, see Gelman et al (2004).

INFERIORITY COMPLEX

Although Sigmund Freud is best known for his influence on the field of psychology, he was also a renowned teacher. Alfred Adler (1870–1937), a student of Freud, broke from Freud’s teachings, criticizing his focus on the sexual. Adler established an approach he called individual psychology, which focused on the individual’s need for fulfillment and power; he is credited with developing concepts such as birth order, quest for significance, mental life, and a variety of complexes including the inferiority complex. Adler suggested that the two needs children have to master are inferiority (or the will for power) and the need for social approval. According to Adler, people are constantly striving to be powerful, and feelings of inferiority (or weakness) often pull them into a consuming state of self-interest. It is important to note that, for Adler, inferiority itself is not negative; rather, it is a normal and even motivating force in life. All humans have some feelings of inferiority and are striving to overcome them. It is when one becomes fully consumed in his or her pursuit of power, or by feelings of inferiority to the point of paralysis, that inferiority becomes a burden. It is at this point that one shifts from having feelings of inferiority to having what Adler called the inferiority complex.

Adler initially conceptualized inferiority with regard to what he termed organ inferiority. In 1907 Adler wrote Study of Organ Inferiority and Its Physical Compensation, in which he theorized that organ inferiority occurred when one bodily organ was significantly weaker than another organ, causing the surrounding organs to compensate for the weakness in the inferior organ and make up for the deficiency in another way. Similarly, Adler suggested that individuals have or perceive that they have areas in which they are deficient—whether physical or psychological. Adler thought that, beginning in childhood, a deep feeling of inferiority is instilled in each individual as a result of the child’s physical stature. In contrast to an adult, a child sees himself or herself as inferior in both physical and psychological abilities. However, Adler thought that the degree to which the child feels inferior is largely the result of the child’s environment and interpretation of that environment. That is, some children perceive that they have more deficiencies or greater weaknesses because of the challenges they face, the way they interact with the adults in their lives, or the negative messages they get about their abilities. These children come to believe that they are inferior based on their perceptions of themselves and their life, not based on measurable or concrete criteria.

As adults, individuals also perceive areas of deficiency or weakness. These perceived weaknesses may result from life experiences (e.g., receiving a low test score) or from critical statements made by important others (e.g., being called stupid). Regardless of how the perceived deficit is brought to the individual’s awareness, once the individual identifies an area perceived to be a weakness, he or she tries to compensate for those feelings of inferiority and achieve power. However, if this compensation does not have the desired result, the individual may become fully focused on the inferiority and develop what Adler called the inferiority complex.

According to Adler, the inferiority complex is a neurosis; the individual is fully consumed in their focus on the inferiority. It is a magnification of the normal feelings of inferiority, and results when strivings to overcome inferiority are greatly hindered. Individuals who struggle with feelings of inferiority may rate themselves in some area important to them as a 5 on a scale of 1 to 10, when they would aspire to a 6 or 7. In contrast, those with an inferiority complex may rate themselves as a 2 on a scale of 1 to 10 when they aspire to a 9. Those with an inferiority complex may also believe that there is no hope of ever reaching 9. The perception of one’s shortcomings is an important aspect of this complex. That is, it matters more where individuals perceive themselves to be than it does where they actually are.

An individual with an inferiority complex is often overwhelmed, and as a result, the inferiority complex can become as consuming as an ailment or disease. Individuals may become manipulative in order to try to get others to give them the affirmation they are looking for, or they may try to use their deficiencies to get special attention or accommodation for circumstances that they are actually capable of handling or overcoming on their own. Those with inferiority complexes may be self-centered, depressed, incapable of development, compliant, shy, insecure, timid,
and cowardly. They may be unable to make decisions for themselves and lack courage to move in any direction unless they are guided by others. Normal feelings of inferiority propel individuals toward solving and overcoming problems. Individuals typically do all they can to improve the situation and rid themselves of the feelings of inferiority. However, individuals with inferiority complexes are prevented from being able to solve or overcome problems. Indeed, Hertha Orgler in Alfred Adler: The Man and His Work (1973) wrote that Adler defined the inferiority complex as an “inability to solve life’s problems” (p. 56). Adler believed that an inferiority complex, once established in an individual, would be a continued and lasting psychological struggle.

Adler’s individual psychology theory is one of the mainstays in psychological thought. However, one controversial aspect of his theory is that it tends to be more conceptual than scientific—that is, it is subjective rather than objective. Further, many of Adler’s concepts seem to be based on anecdotal evidence from his own life rather than on evidence integrated as a result of scientific research. There are many other theories that also are difficult to test empirically (e.g., object relations and gestalt), and it is likely that Adler would argue that those were his experiences and that other people could provide anecdotes of their own to corroborate his theories.

INFERTILITY DRUGS, PSYCHOSOCIAL ISSUES
Throughout American history, sociocultural expectations and norms have been that adults of childbearing age should procreate and become parents. This expectation presumes that every couple is able to have children and that they are broken, defective, or flawed if they are not able to conceive. While infertility is a medical problem, a variety of emotional responses are often associated with one’s inability to have children. Individuals may begin to struggle with feelings such as anger, stress, disappointment, depression, anxiety, and low self-esteem. These negative emotions, in addition to the often invasive medical procedures associated with trying to become pregnant, can have a significant impact on individuals as well as on their relationships. Advances in assisted reproductive technologies as well as a variety of adoption and surrogacy arrangements now make it possible for some previously infertile individuals and couples to achieve parenthood. However, the psychological and sociocultural issues with regard to using outside interventions to become a parent can be problematic.

It is estimated that infertility affects approximately 6.1 million women and their partners in the United States, about 10 percent of the reproductive-age population (National Survey of Family Growth, Cycle IV 1995). Infertility is defined as the inability of a couple to achieve a pregnancy leading to a live birth after one year of regular, unprotected sexual intercourse. Infertility is experienced equally by males and females. Forty percent of infertility is due to what is termed “male factor,” 40 percent is due to “female factor,” and the remaining 20 percent is shared between the couple. In nearly 90 percent of cases, a clear medical diagnosis is presented to couples after an infertility evaluation. The remaining group, 10 percent, is diagnosed with “idiopathic” or medically unexplained infertility. Even with a clear medial diagnosis of the etiology of infertility, it is estimated that only 30 percent of all couples who receive medical treatment for infertility successfully attain a live birth.

The medical diagnosis of infertility can lead to profound emotional, relational, and sexual distress and social stigma in addition to challenging financial, legal, and medical treatment decisions. The negative feelings and difficult challenges can be profoundly disruptive to a couple or individual’s life. In empirical and anecdotal literature, people experiencing infertility often note heightened emotional disturbance (e.g., anger, anxiety, depression, and helplessness), faltering self-esteem, and preoccupation with thoughts about conception. These thoughts and feelings can lead to a disruption in daily functioning as well as changes in sleeping, eating, and moods. Additionally if a diagnosis of infertility is received, there is often little or no societal, cultural, or religious preparation for the impact that is commonly experienced by those struggling to become parents. The duration and intensity of infertility treatment and its failure can increase or exacerbate pre-existing mental health issues, intrapersonal and interpersonal concerns (including domestic violence), alcohol and substance use, and workplace challenges. Issues such as pregnancy loss, miscarriage, stillbirth, chemical pregnancies (pregnancy resulting from in vitro fertilization or other reproductive technology, characterized by low levels of HCG and usually miscarriage prior
to implantation) may also be experienced by those undergoing infertility treatments and clearly can cause undue stress, anxiety, and health problems as well.

During infertility medical treatments, people often experience a variety of extreme emotional responses as they are faced with repeated high hopes of pregnancy crushed by the failure to conceive month after month. Those undergoing infertility treatment might feel overlooked by medical staff, insensitively managed, or overwhelmed by an array of invasive and expensive procedures. Fertility medications rarely are successfully utilized in isolation and accompany the vast majority of common infertility procedures and assisted reproductive technologies (ART), such as intrauterine insemination (IUI), in vitro fertilization (IVF), egg donation, sperm donation, and embryo donation.

The drugs used to treat infertility work by promoting ovulation (ovulation induction) through stimulating hormones in a woman’s brain to prompt multiple eggs to release from the ovaries. Most fertility medications have been safely and effectively utilized for more than thirty years. Common fertility drugs include clomiphene, human menopausal gonadotropins, and bromocriptine. Potential side effects of these medications can include weight gain, hot flashes, mood swings, nausea, breast tenderness, cramping, and ovarian hyperstimulation. Drugs for infertility may result in multiple births, which can be challenging because they increase the likelihood of premature births and babies who may be at higher risk for developmental, social, and psychological complications. Further, conflicting empirical research indicates that women who take ovulation-inducing medications in conjunction with ART might be at increased risk of developing breast, ovarian, or uterine cancers.

As infertility medical technology continues to develop, navigating ethical and legal issues becomes important for both medical and legal policy makers as well as individuals and couples. Increased options for those experiencing infertility continue to be developed. Specialty procedures available through medical treatment include sex selection, screening for genetic anomalies, preimplantation genetic diagnosis (a procedure that can assist couples who have serious genetic disorders such as cystic fibrosis and Tay-Sachs disease), and egg and sperm freezing. While the concept of building a “designer baby” (i.e., one with certain physical or genetic characteristics) tends to get a lot of attention from the media, for most people handling infertility this is a misnomer. The vast majority of people who are trying to conceive simply want to begin or continue building a family in a way that most closely mirrors nonmedical assisted conception.

Infertility medical treatments are typically quite expensive and sometimes financially prohibitive for individuals through private pay. Insurance companies often do not cover infertility treatments, and coverage policies vary by state. Due to the cost of fertility medication and accompanying medical procedures, it is often only the more socially and economically mobile individuals or couples who are able to attempt to undergo medical infertility treatment options in their efforts to have children.

**INFIDELITY**

Alfred Kinsey’s landmark studies of male and female sexuality, beginning in the late 1940s, were the first empirical examinations of infidelity. Following Kinsey, however, little research was done until the 1970s, and it was not for another decade that the first reliable estimates of the prevalence of infidelity were obtained. Thus, research on infidelity, while growing, is still in its nascent phase.

**DEFINITIONS AND PREVALENCE**

*Infidelity* is a broad term that encompasses a variety of behaviors. Because of this, social scientists have used innumerable descriptors to more precisely capture the varieties of infidelity (e.g., nonmonogamy, extradyadic involvement, extramarital coitus). Terms fall broadly into two classes: (1) sexual infidelity, which specifies a degree of
Infidelity

physical intimacy with someone other than a committed partner; and (2) emotional infidelity, which indicates a channeling of resources such as love, time, and attention toward someone other than one's partner. An additional term, intimate betrayal, has been suggested to describe the experience of specific relationship standards and expectations being violated. These terms are not mutually exclusive, and any given extradyadic involvement may include one or all of these aspects of infidelity to varying degrees.

Nationally representative surveys of the American population have focused on the prevalence of sexual intercourse outside of marriage. These studies have found that approximately 22 percent to 25 percent of men and 11 percent to 15 percent of women report at least one instance of extramarital sex while married, though up to 34 percent of men and 19 percent of women in older cohorts reported infidelity. Moreover, these figures almost certainly represent the lower bounds of actual acts of infidelity, as some individuals are unlikely to be candid about such intimate details of their lives. Research using procedures with greater anonymity (e.g., computer assisted self-reporting as opposed to face-to-face interviews) support this conclusion.

CORRELATES AND THEORIES OF INFIDELITY

Gender differences have received more attention than any other correlate of infidelity in the empirical literature. Overall, men are more likely to have an affair, though this finding is strongly dependent on the cohort of the individual. Gender differences are greatest in the baby-boom generation (those born just following World War II [1939–1945]) and reduced in younger cohorts; individuals born during the 1960s and later do not show gender differences in the rate of infidelity. The shrinking gender difference may reflect basic demographic changes, particularly the greater number of women in the workforce, a common place to meet affair partners.

While the overall interest remains low, more men express a desire for infidelity and the active pursuit of an affair relationship. Nonetheless, the majority of both sexes expect sexual monogamy in their marriage relationships. In addition, men's affairs tend to be more sexual and less related to the satisfaction of their marriage as compared to women, while women's affairs tend to be more emotional and described as long-term, loving relationships. It remains unclear how these gendered aspects of infidelity may be shifting with the changing rates of infidelity across generations.

Factors related to infidelity can be organized in terms of their source (i.e., involved partner, spouse, marital relationship, and context). A history of divorce, permissive attitudes toward infidelity, lack of religiosity, being African American, and poor interpersonal connections in the marital relationship have consistently shown a positive association with infidelity for involved partners. Factors related to the spouse of an unfaithful partner remain an interesting but little researched area. In terms of the marital relationship, marital distress, sexual dissatisfaction, imbalances of power, cohabitation prior to marriage, and highly autonomous marital relationships have been linked to infidelity, as has marrying at a young age and the length of the marriage. Some contextual factors include opportunity, travel, income, the availability and willingness of partners, and the individual's perceptions of societal frequency and acceptability of infidelity.

A variety of theories have been put forth to account for infidelity, with evolutionary psychology receiving the most attention. This theory posits that men's desire for sexual variety can be explained by natural selection (i.e., men historically have sought reproductive success by gaining access to a variety of women). As such, men are more bothered than women by sexual infidelity because it threatens this goal. Women, on the other hand, find emotional infidelity more disturbing because it threatens the male's commitment to protecting and providing for a woman and her offspring. Cross-cultural research demonstrates that men consistently both have more affairs and show greater distress due to sexual affairs than women do. However, there is tremendous variability across cultures in the rate of infidelity, underscoring the important influence of cultural and societal factors.

RESPONSES TO INFIDELITY AND THERAPY

Although some therapists have suggested that infidelity may at times be helpful for individuals and couples, the empirical literature strongly supports the negative consequences of infidelity. Extramarital affairs are reliably associated with increased marital distress, conflict, and divorce. When an affair is revealed, the spouse of the person who had the affair is often angry, humiliated, and depressed, and symptoms of post-traumatic stress disorder may be present, such as intrusive thoughts, hypervigilance, and real or imagined images of their spouse with the affair partner. In addition, infidelity can indirectly expose the uninvolved partner to sexually transmitted diseases, including HIV/AIDS. This is a significant risk when the affair relationship involved drugs or alcohol, which in turn reduces the likelihood of safe-sex practices. Research focused on the reactions of the involved spouse have been limited, but there is some evidence that after an affair is revealed he or she experiences increased depressive symptoms, a lower sense of well-being, and greater guilt and shame.
Infidels

Beyond individual reactions to an affair, there are two broad outcomes for the marital relationship: staying together or getting divorced. Relationship dissolution can be influenced by the nature of the infidelity (e.g., degree and type of involvement, how the affair was discovered), cognitive factors (e.g., attitudes toward infidelity, meaning attached to the affair), and aspects of the marital relationship (e.g., length of marriage, level of commitment, quality and satisfaction with the marriage).

Not surprisingly, marital therapists have described infidelity as one of the most difficult problems to treat—and one of the most damaging for a relationship. In spite of this, there is a paucity of empirical research on marital therapy for infidelity. What research does exist is somewhat optimistic, however. Couples that have experienced an affair and then pursue marital therapy show strong improvements during therapy, including greater marital satisfaction, reduced trauma symptoms, and greater forgiveness in the uninvolved partner. However, it is challenging to generalize these findings to the wide prevalence of infidelity, as only a small number of studies have focused on therapy, and because many couples do not seek therapy after an affair has occurred.

INFIDELS

Any society with a more or less coherent cultural boundary tends to have an exclusionary notion of the outside and hence of otherness; the more inclusive the notion of membership, the more intense the notion of an outside.

With the collapse of the ancient world, the problem of otherness became closely associated with the development of the monotheistic and prophetic religions of Judaism, Christianity, and Islam. Because Yahweh was a jealous God, there was a sacred covenant between God and the tribes of Israel, which excluded those who worshipped idols and false gods. In Islam, there is a clear division between the household of the faithful (dar al-islam) and the sphere of war (dar al-harb). The notion of an external world of infidels is captured in al-Kafirun, the title of the 109th sura (chapter) of the Qur’an, which opens with, “Say, oh infidels.” This Meccan chapter expresses the idea that religion should be freely chosen, stressing the devotion of the Prophet Muhammad (c. 570–632). This division between believers and infidels has, if anything, been reinforced by twentieth-century interpretations of a struggle (jihad) against unbelievers—an interpretation fully articulated in the writings of Sayyid Qutb (1906–1966), a radical member of the Egyptian Muslim Brotherhood. Qutb called Muslims to struggle against the darkness or barbarism of the West (jabiliya) and to reestablish the true Islam of the early community. Islam also has a definite notion of the dangers of apostasy (Ridda). When the Prophet died, many tribesmen assumed that their contract with the Prophet was concluded, but the Apostasy War was fought to maintain the coalition of tribes that formed the political basis of early Islam.

In Christianity, a universalistic orientation that recognized the “other” was contained in Paul’s letters to the Galatians and Romans, which rejected circumcision as a condition of salvation. Because the uncircumcised were among the righteous, the message of Jesus had, at least in Pauline theology, a universal significance. However, the church developed a body of theology dealing with the problem of infidelity, making a clear division between the faithful who are baptized and follow the teaching of the church and those who are outside the faith. The term pagan connotes both the uncivilized and illiterate who live outside the city (the heathens) and those who live outside the church. Paganus stood for “civilian” as opposed to miles, “soldier,” and hence the Christians of Roman times came to call themselves the milites or “soldiers of Christ” who struggle against sin and evil. The modern Salvation Army continues this notion of soldiers of Christ. The idea of an infidel is somewhat different, signifying a distinction between somebody who for whatever reason is ignorant of the Christian message and somebody who has actively rejected the promise of salvation in the life and teaching of Jesus. This notion of infidelity did not become well established in English until the early sixteenth century, when it described active opposition to Christianity on the part of Jews or “Mohammedans,” as Muslims were mistakenly called. As a result, infidel became a term of opprobrium. The infidel in Catholic doctrine is to be
distinguished from heretic. While the infidel is somebody who does not believe in the doctrine at all, a heretic is somebody who falls astray from true doctrine by, for example, denying the divinity of Jesus. The problem of the heretic is not one of unbelief so much as rival belief.

Judaism also has a notion of heathens (specifically pagan gentiles) who are called acum (an acronym of Ovdei Cohavim u-Mazzaloth) or, literally, those who are “star-and-constellation worshippers,” or idolaters. Heretical Jews are minim or sectarian people, such as the early Christians. The Hebrew term kefer, which is cognate with the Arabic kafir, is applied to apostate Jews. The various attempts to reform Judaism in the nineteenth and twentieth centuries, such as the Conservative and Orthodox movements, have revived Jewish culture, once more giving greater emphasis to orthodox piety and to the separation of Jews from gentile culture.

The conception of infidelity as a theological condition is therefore peculiar to the Abrahamic religions, which specifically, as a result of strict conformity to monotheism, reject the worship of idols and condemn pagan rites that are designed to placate the gods. Because they claim to be based on a unique revelation and promise of redemption, they have logically and necessarily an exclusive view of the “truth.” These religions, especially Christianity and Islam, developed as a result of a strong commitment to evangelism and the conversion of pagans to the true religion. Both Christianity and Islam recognized in their formal teaching that conversion has to be voluntary. In Islam, for example, in verse 256 of Surat al Baqara, the Qur’an states, “There is no compulsion in religion.” Roman Catholic doctrine similarly recognizes that conversion must be voluntary, and even the baptism of children cannot take place without consent unless they are in imminent danger of death.

The idea of paganism and infidelity is largely absent from the so-called Asian religions of Confucianism, Buddhism, Hinduism, and Shintoism, which either reject the idea of a single “high God” or tolerate various forms of polytheism and animism. A division between the moral and rational faith of Protestant Christianity and the popular rituals of the non-Christian world, which attempt to placate the gods to secure human prosperity, was developed in Western philosophy in Immanuel Kant’s (1724–1804) Religion within the Boundaries of Mere Reason (1793). The Enlightenment substituted rational/irrational for the original true believer/infidel distinction. However, this distinction also raises the question as to whether monotheistic traditions are inherently more intolerant of diversity than other religious traditions, and hence legitimize violence against infidels. The New Testament sense that the Jews rejected their savior and crucified him has been regarded as the foundation of anti-Semitism in the medieval and (to a lesser extent) the modern world. Christian and Muslim notions of infidelity are assumed to be the cultural context for crusades and holy wars. In the twenty-first century, religious fundamentalism, dividing the world into true believers and the rest, is associated with the growth of religious nationalism, violence, and terrorism.

INFLATION

Like many topics in economics, the concept of inflation—defined as an overall increase in the general price level of goods and services measured against a standard level of purchasing power—is subject to considerable disagreements among economists, highlighting the important differences between orthodox and heterodox economics. There are three important areas of disagreements. First, there is no consensus on the possible causes and consequences of inflation, even in a small, open economy. Second, economists disagree on the advantages of fighting inflation; in other words, should inflation-reduction be the primary goal of macroeconomic policy? Finally, economists disagree on the policies to be used to combat inflation. Indeed, in recent years there has been widespread agreement over interest rate–tightening as a way of fighting inflation, but such policies are misplaced, because they produce lower economic activity and higher unemployment.

Inflation is measured by keeping track of the changes in the prices of a number of items within a specific basket
of goods and services over a given period of time, ignoring any improvement in quality. There are a number of ways of calculating inflation. For instance, the consumer price index (CPI) measures the changes in the prices of goods and services generally purchased by consumers. It is by far the most commonly used measurement. Other measurements include the gross domestic product (GDP) deflator, which measures inflation over the entire domestic economy.

THE ORTHODOX APPROACH AND INFLATION

For orthodox economists, inflation carries important costs because there are advantages to lower inflation. Among the costs, orthodox economists claim that inflation erodes the value of money, and economic agents are frustrated in making their consumption and saving decisions; it encourages speculative investment to the detriment of productive investment; and it represents hardship for those on limited incomes or on incomes that are not indexed.

Among the benefits of low inflation, orthodox economists point to the ability of economic agents to make better, more informed, long-term decisions given the relative stability of purchasing power. For instance, because inflation is considered to lower the value of money, low inflation restores confidence in money: By reducing future variations in the price level, households can better plan their consumption and saving plans and regain confidence in the future value of money. Economists also claim that low inflation lowers nominal and real interest rates, and therefore produces overall stability of the economic system, as low inflation is self-reinforcing.

In orthodox economics, the principal cause of inflation is excess demand in the goods and/or labor markets, a direct result of scarcity in both markets. Whenever aggregate demand is greater than aggregate supply at any given price, the overall level of prices of goods and services will tend to increase in order to eliminate the excess demand: Inflation is demand-led. This is the necessary consequence of interpreting macroeconomics through the use of aggregate demand (AD; the total demand for goods and services in a national economy) and aggregate supply (AS; the total supply of goods and services in a national economy) analysis, interacting in price-output space. If there is a positive relationship between prices and output, it is because the AS curve is nonhorizontal. In this sense, both output and the price level are the result of AD-AS interaction. This analysis leads to an understanding of the role of prices in orthodox theory as a mechanism that guarantees market clearing.

In fact, irrespective of the specific neoclassical or orthodox approach, excess demand is always a central focus of inflation. Indeed, for monetarists, the growth of the money supply over and above the growth of output is seen as the principal cause of inflation. In their words, inflation is “always and everywhere a monetary phenomenon” (Friedman 1963). For monetarists, increases in the money supply always precede increases in prices. This results from the belief that the money supply is an exogenously determined quantity, independent of the needs of the economic system. The money supply is simply imposed on the system by the central bank, which can choose at will the growth rate of the money supply. Hence, whenever the central bank is pursuing expansionary policies, it allow the growth rate of the money supply to exceed that of output, resulting in “too much money chasing too few goods,” the inevitable result of which is higher price levels. This view is based on the well-known quantity theory of money.

Keynesians, however, although they do not deny the role played by the exogenous money supply, place the emphasis primarily on output, given the relationship between output (unemployment) and inflation as embedded in the Phillips curve, according to which there is a trade-off between unemployment and inflation: Lower unemployment implies higher inflation. In other words, fighting unemployment comes at the cost of higher inflation. As unemployment decreases, wages tend to increase, raising prices in the process.

An obvious question is what then may cause excess demand? The answer lies in expansionary monetary and fiscal policies—in other words, the central bank and the state. In addition to an expansionary monetary policy, inflation arises because governments pursue an expansionary fiscal policy. Inflation arises either because the deficit is financed by printing money, or because an increase in fiscal policy will increase output, spending, and therefore demand for goods and labor.

Given the above discussion, the policy solution to contain inflation is to reduce the pressure on prices by reducing overall demand in the economy. This means limiting the growth of the money supply and reducing fiscal expenditures: Policymakers need to adopt responsible, sound policies. For Keynesians, this implies higher unemployment and lower wages.

THE HETERODOX APPROACH AND INFLATION

For heterodox economists and post-Keynesians in particular, excess demand is not the principal cause of inflation, largely because the economy almost always produces at less than full capacity: There is almost never an excess demand for goods, and similarly, there is but rarely scarcity in the labor market. Post-Keynesians and heterodox economists nonetheless acknowledge that demand
may have some influence on prices, but it is considered to be small and indirect. This statement has direct implications for and stands in stark contrast with neoclassical theory. For instance, one of the main consequences is that fiscal spending or excess growth of the money supply cannot be a causal or direct influence on prices and inflation. Indeed, for heterodox economists, money is never a cause of inflation. This is because the money supply is endogenously determined: Excess money cannot exist (Lavoie 1992; Rochon 1999). In other words, the money supply is not determined by the central bank, but rather by the needs of production.

In contrast to orthodox theory, therefore, the principal cause of changes in the price level is increases in the costs of production. In this sense, heterodox economists adopt a cost-push approach to inflation. That said, orthodox economists do not deny the importance of costs in determining changes in the price level, but there are important differences between the orthodox and heterodox approaches. For the former, changes in cost are usually the result of “supply shocks,” which occur only occasionally, such as a sudden increase in the price of oil or some unexpected and unforeseen event abroad. For heterodox economists, however, changes in the costs of production are the primary and dominant cause of inflation, and are part of the normal operations of contemporary economic systems.

For heterodox economists, however, inflation is not merely cost-driven, but it is also the result of conflicting claims over the appropriate division of income. Markets are characterized by dynamic interactions between macro-groups, such as workers, firms, and rentiers, each vying to get a larger share of income: Workers want higher wages, firms want higher profits, and rentiers want higher rents. In this sense, inflation is the result of a struggle over the distribution of income. It can arise largely from either a wage-wage spiral or a wage-price spiral, or from the attempt by firms to impose a given rate of return. In this sense, two important features of the heterodox explanation of inflation are collective bargaining and administered prices.

For instance, in formalized conflicting claim models, such as that described by Louis-Philippe Rochon and Mark Setterfield (2007), workers have a target wage share that they consider fair, equitable, or just. And although workers in general want to increase their overall nominal (or real) wages, they also want to maintain their social standing and their wages relative to other workers. If a specific group of workers negotiates higher wages, other groups may also demand higher wages in order to maintain their relative standing in the social order, fuelling the inflationary spiral. In turn, this wage-wage spiral implies higher costs of production for firms, which may try to pass on these costs to consumers through higher prices, which in turn will reduce real wages and lead to possible demand for higher wages in the future.

Moreover, firms may want to increase their standard rate of return to historical levels (Lavoie 1992). Firms may experience lower than normal returns and may want to increase their mark-up in order to bring their rate of return in line with more traditional levels, raising prices in the process. This in turn will lead to lower real wages, and workers may demand higher nominal wages to compensate.

Firms may be able to raise prices because, unlike in neoclassical theory, prices are administered: Firms set prices according to a mark-up over costs of production, not by competitive forces in the economy. In other words, firms will impose a rate of return over and above the normal costs of production, primarily wages and interest costs on debt, because they target a certain margin of profit.

In the end, whether firms or workers succeed in imposing their wills depends on the relative power of workers vis-à-vis firms in the wage bargain, and the relative power of firms in commodity markets. In turn, these powers vary according to the economic cycle or with the market structure. For instance, during periods of growth when unemployment is low, workers have greater power and may be able to demand higher wages. As for firms, brand loyalty, advertising, and the complexity of products give them greater power over prices (Lavoie 1992).

Finally, conflict also arises between firms and rentiers, who also want to increase their share of income. When the central bank increases interest rates, satisfying rentiers, firms may increase their mark-up and prices, and thus lower real wages. This also highlights an indirect conflict between workers and rentiers. For John Smithin (1994), rentiers are at the heart of the conflict. It is in this sense that heterodox economists see the rate of interest as a distributive variable.

The same analysis can be used to analyze deflation, that is a generalized decrease in the overall price level. In a conflicting claims model, one can assume that during periods of high unemployment, when workers are more desperate for work, they would be willing to work at wages lower (lower target wage) than what firms would be willing to offer in an effort to squeeze themselves into the labor market. With these downward pressures on wages, it remains possible for firms to lower prices, although deflation remains a rare phenomenon in contemporary developed economies since World War II, where the general trend on prices has been upward.

Similarly, the cost-plus approach and conflicting-claims model can be used to explain periods of hyperinflation (Camara and Vernengo 2001). For instance, in the case of inter-war Germany, the most probable cause of
Hyperinflation was the extreme costs of war reparations imposed by the Treaty of Versailles, a collapse of German exports, a depreciation of the currency, and higher prices. One may further assume that workers may resist the resulting important decline in real wages, along the same lines as described earlier. In the end, conflicting claims and distribution are key components of the explanation of both inflation and hyperinflation.

Heterodox economists also stand in contrast with orthodox economists in proposing policy remedies for fighting inflation. Three questions arise. First, should inflation always be the primary target of economic policy? Second, should the central bank be solely responsible for pursuing anti-inflationary policies, as has become the case in recent years? Finally, how can inflation be tamed?

Heterodox economists believe that too much emphasis is placed on fighting inflation, to the detriment of fighting unemployment and growth, which are the central focus of heterodox policy. As excess demand is not a direct contributor to inflation, there is no reason to believe that economic growth necessarily accompanies inflation. Moreover, because money is not seen as the principal cause of inflation, and also because there is only an indirect link between interest rates and inflation, heterodox economists do not see the central bank as the primary institution to fight inflation. In fact, central bank policy exacerbates the inflationary process.

Nevertheless, to fight inflation, heterodox economists propose a two-prong policy. First, we need de-emphasize the role of the central bank by setting the real interest rate at a “fair” level (equal to the growth rate of labor productivity), thereby limiting the influence of the rentier class. Second, we should adopt a permanent price and income policy in order to limit the increase in wages and prices.

Informal Economy

All modern states regulate the economy; they also establish what goods and services are not, strictly speaking, part of this formal “economy.” Informal economy can refer to either or both of these residual spheres. It is therefore useful to discuss the term from the perspective of who uses it and with reference to what kind of society. For some economists a sphere such as the household-based family is not an economic sphere because no finite transactions can be observed therein. Sociologists, conversely, use the term to expose a broad array of unrecorded work. Thus, besides transactions unregulated by government, they include practices, such as housework, domestic consumption, and caregiving, that fall outside “the economy” as measured by gross domestic product.

Perspectives on Informal Economy

Emphasizing “the [low] degree of rationalization of working conditions,” the anthropologist Keith Hart (2004, p. 8) first used the term informal economy in 1971 to describe the casual work of the poor in Accra, Ghana (Hart 1973; see also Geertz 1963). While Clifford Geertz and Hart worked from a Weberian understanding of economic rationality, the term informal sector was picked up by international agencies and development economists in
terms of quantitative degrees of scale, productivity, and income. Because the term was used to replace earlier understandings of “developing” societies in terms of “dual economies” (Lewis 1955), its initial usage was confused. Thus relatively independent formal and informal sectors now replaced the older notion of modern and traditional sectors of a national economy in which market forces at work in the one were distorted by custom in the other. Development in both formulations was seen to occur as the more dynamic sector expanded to absorb ever larger swaths of the more backward one. The theoretical vagueness of the new term led to criticisms (Bromley and Gerry 1979) that, combined with the empirical failure of these prognoses, led to marginalization of the term until the dawn of the twenty-first century.

Twenty-first century analyses stress the crucial interplay between formal and informal economies in especially two ways. Firstly, there has been a general shift throughout market economies from formal institutions with sharply defined boundaries and functions to those with fuzzy boundaries and highly adaptable functions. As a result some writers prefer the notion informalization process rather than use of a set of criteria to distinguish two different spheres of a society (Castells and Portes 1989). Secondly, analysts have increasingly focused on the degree to which different components of the informal economy are crucially linked to the so-called formal economy through putting out to homeworkers and subcontracting to informal workshops, while other components remain relatively less directly linked (Chen 2005).

Interest in the informal economy is widespread among development practitioners and international- and national-level policy makers as well as scholars in the various social sciences. Since it is inconceivable that there would be no informal practices in an economy or society, the way one understands such practices is likely to result from the kinds of settings on which one focuses. Among these are developing societies, socialist command regimes and their transformation, welfare regimes, and neoliberal regimes.

SETTINGS OF INFORMAL ECONOMY
A primary concern in the literature on “developing” societies is whether or not the informal economy is a benefit or a handicap. Insofar as a low capital to labor ratio is almost a definitional feature, it can be argued that a large informal economy reduces a country’s average productivity; by avoiding start-up and running costs, it also effectively competes with firms paying taxes and legal fees. By contrast, insofar as it is, again almost by definition, the way poor people get by, the informal economy maximizes employment opportunities. In 2000 the Peruvian econo-

mist Hernando de Soto therefore advocated its encouragement through the introduction of a legal code more appropriate to current informal practices. His views, however, remain controversial.

Some commentators argue that these third world informal economies reflect a “weak state” that is unable to regulate uniformly throughout the polity. Prior to 1989 the reverse was the case for the informal economies that flourished under socialist command regimes, whose pervasive and rigid regulatory practices and intentional use of strategic scarcities provided the seedbed for informal practices. These eventually provided important networks that became the basis for resistance and eventual collapse of these regimes. The informal economy that resulted and now pervades the former Soviet bloc (Russia, Hungary, and so on) must be distinguished from socialist command economies that remain in place but have intentionally reduced the non-commodified socialist sphere. Here informal economy results from opening up ever larger areas of social interaction to market transactions that are nonetheless inconsistently regulated—China being the most vivid example.

In the “developed” capitalist economies, interest in the growing size of the informal economy has frequently been attributed to the failures of welfare regimes either to be comprehensive in their provision of services or to stimulate economic dynamism. For some the state was not providing enough welfare, while for others what it did provide was too costly and too inflexible for the changing needs of capitalism. Thus one argument was that informal practices were taken on by people who were not being properly served by the welfare regime, partly as a result of declining formal jobs and partly as the welfare state failed to provide social citizenship to newly arrived immigrants and established visible minorities. The other argument was that high taxes and pervasive regulation drove both workers and firms into informal, semi-legal channels. Nonetheless, while it is common for economists to correlate an expansion in informal activities with the higher taxes and increased labor legislation of welfare regimes, this makes it hard to explain the striking increases in such practices under neoliberal regimes. In partial explanation, while the former was both ideologically and pragmatically set against informalization, the latter has encouraged an ideal of “deregulation” positively endorsing decentralization, flexibility, and a “self-regulating” entrepreneurial worker—all supposedly features of informal economy.

ACHIEVING DYNAMISM AND REGULATION
Neither a deregulated economy nor a self-regulating economic actor is a sustainable notion, however. Rather, economies are made up of the regulation of productivity
Informal Sector

and exchange, one way or the other, so a major challenge is to discover the means by which both dynamism and regulation are achieved. By nature decentralized, informal economies provide a wide range of sites for regulation and dynamism. These include employer-employee micro-enterprises, sites of self-employment, domestic enterprises, and homework. They also include networks of interconnection between these (as well as the formal economy and state agencies) and longitudinal means for social reproduction—among them supply, distribution and credit systems, and culturally specific forms for the transmission of property. All of these—and a multitude of others not mentioned—provide sites for possible regulation, facilitation, and invention. This in turn calls into question use of the word economy. As “social” factors are used to regulate market exchanges and appeals to cultural (or “family”) belonging are used as a means for regulating labor, the question arises as to whether it is any longer appropriate to refer to the overall phenomenon as an economy at all. There is probably much less distinction between the narrower economists’ view of informal economy and the broader sociological one. One when realizes the extent to which a wide range of economic practices are regulated through cultures of intimacy and trust combined with ideologies of male authority and female altruism, one sees how the goals of intensifying productivity and even controlling quality expand to embrace a wide range of social practices and relationships.

Like other residual terms, the notion of informal economy will continue to be used to sum up what are in fact hugely varied practices. Insofar as these account for as much as one-half to two-thirds of nonagricultural employment in developing countries and one-quarter in the United States (International Labour Organisation 2002), social scientists are challenged to cease conceptualizing these practices as pathological versions of a supposedly “normal” formal economy and instead develop concepts appropriate to a world that has always existed and yet has just begun to command the attention it deserves (Davis 2006).

INFORMATION, ASYMMETRIC

Asymmetric information exists when one participant in trade knows something that the other participant does not know about the quality of the particular good or service they are trading. This violates one assumption of perfect competition—“perfect information” (when market partic-
Participants have all the information relevant to goods’ and services’ quality and price. The canonical example is the market for used cars (Akerlof 1970): The seller knows her attention to the car’s maintenance, but the buyer’s evaluation of the car’s value is limited to the features he can observe and his knowledge of the average quality of this type of car. In this case, the seller has more information about the product’s quality, but there are also markets in which the buyer has more information. When buying health insurance, for example, the buyer knows his own eating, drinking, and smoking habits, and the seller (the insurer) does not have as clear a picture of the buyer’s quality of health.

The concern of the economist or policy maker is that this asymmetry can lead to market failure: The asymmetric knowledge causes less trade between buyers and sellers than would be optimal for society; in the extreme case, only low-quality goods or services are traded. In this case of complete market failure, high quality goods are not sold: Used-car buyers assume (correctly) that only owners of “lemons” want to sell their cars, and insurance companies assume (correctly) that only less healthy individuals desire insurance. Like other market failures, asymmetric information corrupts the price mechanism: If the buyer lacks information (used cars), the market price will be too low for higher-quality exchange; if the seller lacks information (health insurance), the market price will be too high for higher-quality exchange.

Consider a numerical example in the case of used cars to make these ideas concrete. There are two types: high quality cars valued at $15,000 and low quality cars valued at $10,000. These values, common to both buyer and seller, indicate the utility gained from owning a car. If 10 percent of the cars are low quality, then the prospective buyer could assume with 90 percent probability that he is buying a high-quality car and will offer to pay $(0.90)(15,000) + (0.10)(10,000) = $14,500 or less. But at this price, only the owners of low-quality cars will be willing to sell. As a result, buyers and sellers expect only low-quality cars to be available on the market, and those cars sell for $10,000. Sellers of the low-quality cars know who they are, but the buyers do not. This phenomenon explains why a new car loses so much of its value as soon as it is driven off the dealer’s lot.

A similar example illustrating the case of health insurance would show that there is less incentive for the high-quality (healthy) types to buy insurance, which drives up the price of insurance. Only the customers with poor health and higher willingness to pay are served because the insurer cannot sufficiently differentiate between the high- and low-quality types, but the buyers know their own quality of health. Of course, these extreme examples seldom occur because buyers and sellers find ways to mitigate the asymmetric information, as described below.

The similarity between outcomes under imperfect information and some other types of market failure is the existence of a “free rider.” The buyers (in the case of health insurance) or sellers (in the case of used cars) of the lower quality goods are “free riding” on the reputation of the higher quality goods. The increased incentive for low quality goods and services to be traded is known as “adverse selection.” This is also related to, but different from, the concept of “moral hazard.” The distinction between the two is one of timing: Moral hazard describes the incentive, once an individual has health insurance, to behave more recklessly because he no longer faces the full financial impact of addressing medical conditions brought on by his poor health habits.

Asymmetric information is not simply a lack of information. Even though each piece of fruit at the grocery, for example, may hide some information from the buyer, it is hidden from the seller, too, and the market price can reflect this chance of selling and buying poor-quality fruit. We are also not focused directly on some advantage held by the seller of a low-quality car, or an advantage held by an unhealthy purchaser of insurance. The market failure is simply the lack of a market for high-quality goods. If there were perfect information in the market for used cars, for example, then there would be two car markets, one for trading high quality and one for trading low quality.

There are various solutions to this market failure, but they often have their own drawbacks. Experts may provide the inadequately informed party with improved information, but this also increases the transaction cost—and if there is any remaining unknown information, high-quality goods are still difficult to sell. A physical examination may reveal a health insurance buyer’s health to potential insurers. Regulations may require a minimum quality (of cars or physicians, for example) or certification exams (for electricians or plumbers, for example), but this barrier to entry may provide the regulated group with market power. Quality regulations may also inhibit the provision of lower-quality goods and services for which a market (with lower prices) would otherwise exist (with perfect information).

Could the high-quality agents simply state that they have the high-quality product or characteristics? If this statement, or “signal,” is costly for those with a low-quality product or service, then such a solution is feasible. For example, offering warranties is expensive for those selling low-quality cars, but not for those selling high-quality cars. (This solution may face moral hazard problems, as mentioned above.) Likewise, a college degree need not prepare the student for her intended profession in order to be useful (Spence 1973a; Stiglitz 1975), as long as it is dif-
ficult to obtain for those students valued by potential employers. The degree could simply serve as a signal to employers that this student is bright or a hard worker, qualities that would otherwise be difficult for a potential employer to observe before hiring her. Further, the time and effort involved in courting a prospective spouse may also “signal” the love and commitment that would otherwise be difficult to observe before entering into marriage (Spence 1973b).

Another possible market solution is to provide the low-quality types an incentive to reveal themselves through the available contracts (Rothschild and Stiglitz 1976). In the case of health care, insurers provide contracts with lower deductibles that can be chosen by those less-healthy buyers willing to pay a higher premium. Healthy buyers pay lower premiums but a higher deductible, benefiting from their lower likelihood of illness.

INFORMATION, ECONOMICS OF

The primary sources of the tremendous growth of modern economies are technologies (including sociopolitical ones), and these are applications of systems of information. For entrepreneurs, information is a valuable but often costly commodity. Hence for political and business executives and managers, so-called inside information, that is, information that is known to business managers and public policy executives but not to the general public, presents constant temptation for illegal trading.

The absence of information influences markets, especially through the troublesome use of public ignorance, not to mention ignorance of information about technological innovations. The paradigm case for this is Adolf Von Bayer’s discovery of synthetic indigo in 1880, which famously and tragically ruined Indian farmers who grew the indigo plant in ignorance of the innovation. Less drastic but more spectacular was the fall of the price of shares of telephone companies, once deemed gilt-edged, due first to deregulation and then to the advent of Internet telephony; both were made possible by new technologies. The economic value of innovations creates incentives for secrecy regarding them. Patent laws were designed to discourage this secrecy; their success depends on their success as disincentives.

The most important innovation in retail trade was the replacement of haggling with price-fixing, which entails sellers publicizing information about the minimum price they would settle for. Initially motivated by moral considerations, it proved efficient and prevailed in competitive markets. The theoretical basis for it came from Adam Smith (1776), who deemed competition to be the best incentive for efficiency (Smith 1776, bk. 1, chap. 7). He refuted there (Smith 1776, bk. 1, chap. 1) the popular idea of trade as players outguessing one another in a zero-sum game (that is, one player’s gain is another’s loss). Because free exchange rests on expectation of improvement, all parties to it are partners. Trade is not zero-sum game: Specialization raises productivity and imposes trade. Smith’s major recommendation was to cancel protective import duties that protect the inefficient. In contrast, partial equilibrium theory (Marshall 1890), which is the bread and butter of traditional economics, incorporates the assumption that markets are perfectly competitive—that is to say, free of friction. They suffer no constraints, allow free entry, offer perfect knowledge of all relevant information, and incur no transaction costs. As this assumption is obviously false, economic advisers can easily blame friction for the failure of their forecasts. This is an excuse, the right for which is available only to those who begin with informing their clients of it. Lionel Robbins in 1932 stressed that this makes their economic forecasts shear speculations, unlike the ones based on generalizations about observed regularities. This then resembles the distinction that Frank Knight (1921) and John M. Keynes (1921, chap. 26) made between risk and uncertainty. Unlike uncertainty, risk assessments rest on regularly observed probabilities. What information then can we have on the probabilities that affect markets? This is a vast field, as friction is blamed for so many aspects of the market untreated by the standard models yet given to statistical studies, including changes of tastes, unemployment, market fluctuations, money markets, and even markets for innovations.
The earliest studies of imperfect competition were the models for monopolistic competition (Chamberlain 1933; Robinson 1933). Friction can be viewed as space-time dependent monopoly (and often also vice versa). Kenneth Arrow and Gerard Debreu (1954) offered an economic-equilibrium model that allowed for friction, including information asymmetry, the asymmetry being in one partner to any given transaction having more relevant information than the other. They ascribed to each transaction space-time coordinates and its own characteristics, thus allowing for a diversity of market situations that permit the study of transitions from one market situation to another, including improved information systems and innovations. Particular commodities, such as secondhand cars and risky investments, invite the misuse of information asymmetry, which is troublesome. By contract, ignorance of prices of fairly standard commodities is far less troublesome. Where asymmetry is harmful, as in real estate deals, prospective customers usually examine matters more carefully. The literature shuns the study of the most blatant information asymmetry, namely that of experts. A partial remedy for this is the use of a second opinion, and this is why insurers support it. There is also the matter of conflict of interest, conspicuous in the cases of accountants who examine the books of their clients and of teachers whose grading of their students is inevitably also grading themselves (Flexner 1910). In medicine, informed consent, though legally required, is seldom practiced. To improve matters it should apply not only in treatment of disease but also in diagnosis and from the very first meeting, so that patients will be able to acquire vital information from their physicians (Laor and Agassi 1990).

Information on probabilities helps determine insurance rates. Competition should force the insurance to render premiums fair. Yet all projections are imperfect. Catastrophic deviations from estimates force those who rely on these estimates into bankruptcy. The network of insurance systems that safeguards any subsystem from collapse raises the likelihood of collapse of the whole system, however. For as the saying goes, there is no insurance against epidemics. And the epidemics may be due to some information, misinformation, or even disinformation.

The most valuable information concerns the outcome of tests of theories on valuable matters. Before daring to apply a theory, one must test it to prevent causing too much harm. Information leading to tests of theories is harder to come by in the human sciences than in the natural sciences. It is hard to test even educational theories in experimental classes because conducting tests in classes may be dangerous for the pupils. The same holds true for medical information, and this is why its procurement requires certain precautions guided by the Helsinki Accord and similar constraints. There is nothing to inform the seekers of information regarding education, even though its importance for global politics is all too obvious. Milton Friedman estimated that returns from investment in education are highest and explained the reluctance of entrepreneurs to invest in education as a lack of information (Friedman and Kuznets 1945).

The absence of elementary information forces social researchers to resort to complex theoretical and testing techniques, including systems dynamics. This technique employs systems theory, which is the beneficial suggestion that it is often possible to simplify assumptions about complex systems in diverse ways and obtain different sets of test models. In systems dynamics study is centered on inflow and outflow of certain inventory items in system with feedback loops. These studies are simply too complex to study empirically and often even mathematically. Efforts to apply this to markets are still too hard to evaluate.

In the meantime, entrepreneurs insure themselves as best they can against being pushed out of the market by surprising new technologies. Even marginal investments in small laboratories that function as conduits of new information—habitually useless—have often saved firms from collapse.

This brings a new aspect of information to the fore: How does it flow? This question is basic for the information-transfer technologies that now are growing rapidly. Claude E. Shannon (1949) developed information theory to deal with technical questions, such as how much distortion can a telephone cause without the loss of the ability to identify the voice of a speaker? To be applicable to all sorts of information conduction, Shannon examined signal transfer over channels and distortions as the difference between the message in the source and in the target and asked in the abstract, what characterizes the information that is essential? Unusual information is clearly rare, and Shannon equated information with improbability. (Newer studies improve upon this assumption.) Shannon noted that redundant information helps restore a distorted message. Assuming that no message transfer is perfect, he suggested that with no redundancy a message will be lost with the slightest distortion. Hence the often cited advice to be brief must be qualified. The simplest redundancy is repetition; it helps avoid some distortion. All this holds for signals, not for information proper. Information theory deals with the former and is unable to deal with the latter. The treatment of information as signals was a bold step, and it is central to all computerized systems, including the information highway. Thus a computer spell-checker program spots a rare combination of letters and suggests that it is possibly a misspelled word; if misspelling transforms a word to a common word, then the spell-checker program can only spot it by examining not the word but the sen-
The rise of information technology is the outcome of a few developments, beginning with the wish to increase mathematical rigor in response to George Berkeley’s criticism of the calculus (Wisdom 1953), the wish to develop logic as a formal system, and the wish to combine logic and mathematics. All this informed the transition from calculators to computers. Information theory was the peak of this process. The hope to see the brain as a computer must fail, as computers are blind to meanings, but much insight developed this way, leading to exciting developments in brain science, computer science, and even perception theory, all of which have breathtaking applications. The greatest boon to the economy, however, is the rise of the Internet, as is manifest from the tremendous new knowledge industries and the enormous markets for them.

INFORMED CONSENT

The term research refers to a systematic investigation designed to develop or contribute to generalizable knowledge by testing and proving or disproving specific hypotheses. The knowledge gained through research may be important as a basis for the formulation of social policy or the improvement of practice in medicine, education, social services, or other areas. Research may produce information as the result of experimentation that involves introducing some new variable (e.g., a test drug or method of treatment) into the situation and seeing what difference, if any, that new variable makes. Alternatively, research may entail gathering data and drawing conclusions by observing...
things happening naturally (i.e., a natural experiment). In both the experimental and observational methods, research
may involve using human beings as participants who serve
as the sources of data from which the generalizable conclu-
sions are drawn. Especially when human participants are
involved, research must be conducted in an ethical man-
ner, including assurances that the participants have given
informed consent for their involvement.

Principles regarding the proper conduct of research involving human participants have been incorporated into over thirty different international guidelines and ethical codes. The first of these was the Nuremberg Code, adopted in 1947 for Nazi war-crime trials in which defen-
dant physicians tried to justify their horrible actions as sci-
entific experiments. Subsequent ones were spurred on by
various scandals involving the mistreatment of human sub-
jects, such as the forty-year Tuskegee (Non-Treatment of)
Syphilis Study, the deliberate hepatitis infection of resi-
dents at Willowbrook (New York) state hospital between
1956 and 1971, and injection of live cancer cells into
patients in 1963 at the Jewish Chronic Disease Hospital in
Brooklyn, New York. In the United States, Congress in
1974 enacted the National Research Act, establishing the
National Commission for the Protection of Human Subjects in Biomedical and Behavioral Research (popularly referred to as the Belmont Commission). In 1981 regula-
tions embodying some of the Belmont Commission's rec-
mendations were issued by the federal Department of
Health and Human Services (DHHS, but at the time
called the Department of Health, Education, and Welfare).
These regulations have been adopted by other federal agen-
cies as a Common Rule to protect human participants in
any research protocol those agencies sponsor. Also, any
research concerning the testing of investigational drugs or
medical devices is regulated simultaneously by the federal
Food and Drug Administration (FDA).

Research to which these regulations apply must be
reviewed and approved by an interdisciplinary
Institutional Review Board (IRB) and is subject to con-
tinuing IRB oversight. Conducting a research protocol with-
out IRB approval or over IRB objection subjects the
investigator and sponsoring institution to the loss of any
future government funding for the conduct of research.

For any proposed research protocol, the IRB must
ensure (among other things) that informed consent will be
obtained from each potential participant. Potential
participants must be informed of the following:

1. the purposes of the research, its expected duration,
   and the procedures involved;
2. anticipated risks or discomforts, as well as benefits,
   of participation and all reasonable alternatives to
   participation in the research protocol;
3. the extent to which research records will be kept
   confidential;
4. the availability of any compensation and/or
   treatment for research-related injuries;
5. the right not to participate and to discontinue
   participation at any time without penalty.

The IRB also must ensure that participants’ informed
consent is appropriately documented.

The IRB must police the requirement that no human
subject is involved in research unless ethically sufficient
informed consent has been obtained and the prospective
participant has had the chance, without coercion or
undue influence (i.e., voluntarily), to really consider
whether or not to participate. The regulatory provisions
for informed consent in research are basically a codifica-
tion and extension of the common law (i.e., the judge-
made law that evolves on a case-by-case basis) in the
diagnostic and therapeutic setting. Under the common
law, valid consent requires that the individual's agreement
be voluntary, informed, and given by a person with ade-
quate cognitive and emotional capacity. Individual IRBs
are themselves monitored by the Office for Human
Research Protections within DHHS.

Some states have enacted their own, additional laws,
which vary quite a bit, concerning conditions for protec-
tion of research subjects. Moreover, private civil malprac-
tice lawsuits may be brought by an individual participant
against researchers and protocol sponsors for violation of
common law standards regarding the obtaining of
informed consent or other deviations from the acceptable
standard of care under the circumstances.

Ethical researchers owe a heightened obligation to
make certain that meaningful informed consent has been
obtained for research involving especially vulnerable par-
ticipants, particularly when the research consists of risky
experimental interventions. Especially vulnerable persons
in this context include persons with mental disabilities
that impair decision-making capacity, prisoners, children,
and pregnant women. Racial factors must also be taken
into account when considering the need for special pro-
tections for vulnerable groups, because it has been com-
mon historically for researchers to both take undue
advantage of members of racial minority groups by
including them disproportionately in very risky studies,
and to deny them the potential benefits of research partic-
ipation by unfairly excluding them from certain studies.
When a potential research participant is unable to give
valid voluntary, informed consent personally, a surrogate
acting on behalf of the person's best interests may act as
decision-maker.
Ingratiation

Ingratiation refers to behaviors that one enacts in order to be liked by another person. There are many tactics to accomplish this. First, we can show interest in another person by asking questions, paying attention, and singling out the person to make him or her feel special. Second, we can do favors or help or assist a person. Third, we may show support and loyalty. Fourth, we can smile and be friendly, cheerful, and positive. Fifth, we can directly express admiration by flattering people and telling them what we like or admire about them. Sixth, we can create sympathy by talking about things we have in common with someone.

Any behavior that potentially has the effect of enhancing one’s likeability and that is enacted for this reason can be seen as an instance of ingratiation. So, the same behavior (e.g., helping a friend to study for an exam) can be an instance of ingratiation (if you want to borrow the friend’s car later on) or not (if you are just being helpful), depending on the motive.

Different research paradigms have been used to study how people ingratiate themselves and what the effects are. For instance, when looking at the ingratiator’s part, the researcher may instruct participants interacting with someone to make the other person like them, and then examine how they behave. Looking at the target’s end, the researcher may expose participants to an ingratiating actor and examine if they like this person or are easily influenced by him or her, compared with control conditions (e.g., a noningratiating actor, or participants observing the same behavioral episode directed at someone else).

In his seminal book on ingratiation, Edward Jones (1964) noted that the goal of ingratiation is typically instrumental: We ingratiate ourselves to people because we want to influence their behavior in some way (e.g., get a date, borrow money, get a raise, get a good grade). Thus, ingratiation is a strategy for social influence, and it is typically used quite a lot by salespeople. Because people generally want something from people who have more power or status, the typical example of ingratiation is a lower-status person flattering a higher-status person. This type of ingratiation is recognized very easily by observers because the dependence of the ingratiator alerts them to the possibility of ulterior motives.

During the era of slavery this instrumental motive for ingratiation occurred among black slaves who acted in a subservient manner, expressing agreement with white authority figures (called tomming, after the character Uncle Tom from the book Uncle Tom’s Cabin) in order to receive more lenient treatment (e.g., less physically demanding duties) in the hope that eventually they might be watched less closely and be able to escape. Similarly, in a work environment an ambitious employee may act very servile and conforming with respect to superiors in order to be liked and perceived as unthreatening by them, so that eventually he or she can usurp a superior’s position. In instances like these, as in cases of toadyism, the ingratiator is quite aware of his or her goals and the best possible ways to achieve them, and he or she may even have a long-term plan that is carried out with great sophistication.

Often, though, when people ingratiate themselves they are not aware of it. Many instances of ingratiation are unconscious, so people probably ingratiate a lot more than they think. Also, the target of the ingratiation is very often not aware of what is going on; whereas observers tend to quickly notice when ingratiation occurs, targets of ingratiation are less suspicious. So, the effects of ingratiation are generally as intended: The target likes the ingratiator, and is more inclined to do favors for the ingratiator. The ingratiator may not be aware of his own insincerity either, and may get away with the feeling that he and the target get along very well. E. E. Jones called this the “autistic conspiracy”: Both ingratiator and target are not fully aware of the hidden agenda in their interaction (the ingratiator who wants something; the target who is happy to be flattered, satisfying his or her self-enhancement motive), and they simply feel good because they both get what they want. Neither of them is very motivated to look more critically at the interaction.

In addition to instrumental motives (i.e., influencing others’ behavior), there are other motives for ingratiation as well. It smoothes social interaction, as when we don’t tell people everything we think (e.g., a colleague has a terrible new hairdo). Also, if we get along well with people, they will like us and respond favorably to us, which in turn is good for our self-esteem.

INHERITANCE

Pride and Prejudice opens with the proclamation that it is well known that a man with a fortune is in want of a wife (Austen 1991, p. 1). This satirical remark conveys a theme that is illuminated elsewhere in the text: In nineteenth-century Britain, having an inheritance made a man an attractive marriage prospect. While the advantages that inheritances convey to the individuals who receive them may vary across time and across societies, benefits exist. The nature of these benefits and the motives of the givers are two issues that have been discussed extensively in the social sciences literature.

An inheritance can be described as funds or assets that an individual receives from another person at the latter’s time of death. Accordingly, they are monies that individuals come to possess not through their effort in the marketplace, but through their relationships to other people, typically older family members and most often parents.

CONTROVERSIES AND CRITICAL ISSUES

One hotly contested debate about inheritances concerns the extent to which differences in the propensity to inherit and in the amounts inherited contribute to the observed differences in the amount of wealth that different individuals have. This is an important question because it has bearing on the validity of a popular economic theory of saving. Economists’ life-cycle hypothesis attributes an individual’s wealth at any point in time to the process of saving, arguing that individuals compile savings by spending less than they consume early in life so that they will have funds to turn to during retirement. According to this theory, it is an individual’s earnings, age, and other demographic variables that determine the amount of wealth that the individual has. The receipt of an inheritance provides another potential source of wealth, however, and empirical research suggests that its effects may be significant. During the 1980s Franco Modigliani (1988) and Laurence Kotlikoff and Lawrence Summers (1981) offered estimates of the magnitude of funds that U.S. adult children received from their parents. Modigliani put the sum at about 20 percent of the total wealth that individuals possess, while Kotlikoff and Summers argued that the amount was much higher (almost 80 percent). These data are illustrative because of the historical significance of the debate between these three authors. The debate laid the foundation for additional research on inheritances. Moreover, studies that have been conducted since this time routinely provide estimates of the magnitude of wealth transfers across the generations that lie within the range laid down in the Modigliani and Kotlikoff-Summers debate.

A second debate focuses on the motivations of those who give money to others. With this shift in focus comes a change in language. The term bequest is generally used to describe funds that one leaves to others when one dies, while the term inheritance is reserved for characterizing the funds after they have been received. The debate about bequests asks why people leave them. From a theoretical standpoint bequests can be either planned or accidental. Individuals may make deliberate decisions to leave money to their offspring, or bequests may be given simply because individuals who have accumulated substantial wealth that they plan to spend during retirement die before they finish consuming this wealth, thereby unintentionally leaving something for their offspring to inherit.

When a bequest is planned, theory suggests that there are numerous reasons that parents may choose to leave a bequest (Masson and Pestieau 1997). Some scholars argue that they might be used as a device for disciplining children—that parents can use the promise of a bequest and the associated threat of disinheriting their offspring as ways to force members of the younger generation to devote attention to their elders. Other scholars argue that bequests are given for purely altruistic reasons, stating that wealthy parents who have led comfortable lifestyles may leave bequests simply to ensure that their children also can have comfortable lifestyles or to guarantee that the children are protected against misfortune. Because it is hard to test the theories about motives directly, it is not possible to know exactly how many families use bequests as a disciplining device or how many intentionally leave bequests.

A final controversy surrounds the effects that inheritances have on individuals and on society. Because individuals who are wealthy have advantages that individuals who are poor do not, many social scientists argue that inheritances and other intergenerational transfers may have a negative effect of perpetuating inequalities in society. Proponents of this view note that the ability to leave one’s wealth to one’s children allows children from
Inheritance Tax

Wealthy, comfortable backgrounds to be ensured of being fairly wealthy and comfortable themselves, while children in families where parents are too poor to have a pool of savings to leave at their time of death have no choice but to finance all their needs through their own earnings. Sociologists Melvin L. Oliver and Thomas M. Shapiro have been influential in laying out these arguments and in providing qualitative evidence from interviews with individuals who received inheritances that helps researchers understand the processes through which inheritances can perpetuate inequality (Oliver and Shapiro 1995; Shapiro 2004). Studies based on large national data sets containing information from families throughout the United States provide corroborating evidence suggesting that inheritances contribute to racial inequality (Menchik and Jianakoplos 1997).

POLICY IMPLICATIONS

A discussion of inheritance would be remiss without some mention of policy. One question many societies face is whether to tax inheritances. Naysayers often argue that taxing inheritances is inappropriate because it hampers families’ ability to transfer family businesses from one generation to the next. Others argue that given the privilege that inherited wealth conveys, limiting the amount of funds that can be transferred is consistent with ideals of equal opportunity and making it on one’s own. The theoretical debate about bequest motives also has implications for policy. If most bequests are accidental, taxing inheritances should not substantially alter saving behavior. However, if people are motivated to accumulate wealth for the expressed purpose of being able to leave it to their offspring at death, tax policies that reduce the amount that can be transferred after death might reduce saving. How inheritances affect the incentive to work is another important policy issue. The receipt of an inheritance can reduce individuals’ willingness to work (Holtz-Eakin, Joulfaian, and Rosen 1993). This may provide a justification for policies designed to limit inheritances, much in the same way that there was popular support to reform welfare in the United States due to concerns about its effect on work incentives during the 1990s.

INHERITANCE TAX

An inheritance tax is a tax on funds or assets that an individual receives from someone else when the latter dies. Most European countries levy their taxes on bequests from deceased individuals using this type of tax. This is not the only way that a government can tax transfers made from one generation to the next, however. The United States has an estate tax, meaning that the tax assessed by the government is levied on the entire estate before the estate is subdivided among heirs. The difference is more than semantic. Most countries have marginal tax rates that rise as individual income and wealth rise. With an estate tax, a $50,000 estate left to ten heirs will be taxed at the rate that applies for sums of $50,000. With an inheritance tax, each of the ten individuals receiving a share of the estate would be taxed on the $5,000 that they receive. If their marginal tax rate is low, their after-tax proceeds could be much higher than their share of a $50,000 estate that was taxed at a high rate.

In most European and North American societies, policies toward taxing transfers that elders leave their offspring at death have its roots in a pre-industrial, agricultural form of social and economic organization, where land represented the primary form in which wealth was held and social convention dictated that it was important to make sure that a family’s estate remained intact as it was passed from one generation to the next (Delong 2003). As countries modernized, attitudes toward transfers changed, and tax policy evolved simultaneously. For example, the nineteenth century was a period in U.S. history in which the economy was rapidly expanding and land was plentiful.
Accordingly, J. Bradford Delong (2003) notes that Americans began to view inherited wealth with suspicion during this period, asserting instead that to be rich one was supposed to have earned his or her riches through thrift and industry. The shift in attitudes helped to create conditions that allowed for the passage of the first estate tax in 1916, and the tax rates actually have been quite high throughout time, indicating that there have been periods in history in which Americans did not view taxing inter-generational transfers as inappropriate or controversial. For example, during the New Deal era the marginal tax rate on large estates was set at 70 percent (p. 50). However, by the 1990s U.S. attitudes had changed and legislation was passed to phase the estate tax down to zero by 2011.

Why is taxing inheritances or estates so controversial? As with any tax there are trade-offs to contemplate when assessing the likely merits of the tax. Opponents argue that the tax makes it difficult to transfer a family business from one generation to the next, although policymakers presumably can prevent this outcome by setting an exemption for “small” estates. A second potential cause for concern exists because economic theory suggests that taxing estates or inheritances might reduce individuals’ propensity to save. If individuals save because of a bequest motive, one expects them to save less during their lifetime if they fear their savings will be taxed by the government rather than being passed on fully to their heirs. However, the ability to receive an inheritance can also distort behavior. Theory suggests that individuals who receive an inheritance have incentives to reduce their work effort. This distortion to a labor-supply decision provides an argument for levying a tax on inheritances or estates.

INIKORI, JOSEPH
1941–

Historian Joseph E. Inikori was born in Nigeria’s Delta state in 1941. He obtained his undergraduate degree in 1967 from the University of Ibadan, where he embarked on a PhD program in 1968. A special arrangement allowed Inikori to study at the London School of Economics from 1969 to 1971 under the direction of A. H. John (1915–1978), a preeminent scholar of the early modern English economy. Inikori obtained his PhD in history there in 1973.

After a brief stint as an assistant lecturer at the University of Ibadan (1972–1973), Inikori was appointed lecturer at Ahmadu Bello University in Zaria, Nigeria, in 1973. In October 1981 he was promoted to the post of professor of history and subsequently became chair of the History Department. During this period, Inikori received two prestigious fellowships to English universities: he was named a visiting fellow at the London School of Economics (1974–1975) and he won the John Cadbury Fellowship at the University of Birmingham (1980). In 1989 Inikori became a professor of history and associate director of the Frederick Douglass Institute (1989–1998) at the University of Rochester in New York after serving there for a year as a visiting professor. In 2001 Inikori became the University of Rochester's director of graduate studies, in which capacity he was pivotal in the creation of the doctoral program in global history.

Inikori's research has been essential to the growth of scholarship on the Atlantic slave trade. International interest in quantifying the Atlantic slave trade erupted after the appearance of Philip Curtin's The Atlantic Slave Trade: A Census (1969), a groundbreaking work presenting a systematic estimate of the trade that was significantly lower than most previous estimates. Using newly discovered evidence in British customs records in a 1976 article, Inikori was one of the first scholars to revise Curtin's estimate upward. Publishing numerous articles and presenting papers at many conferences, Inikori has made an invaluable contribution to the literature on quantifying the slave trade.

Inikori has also examined the economic aspects of the slave trade, particularly its market structure, profit levels, hazards, and financial relationships. All of Inikori's works on this subject revolve around the central factor informing his multifarious research—the preoccupation with placing the Atlantic slave trade in its proper context in the development of the global economy. Inikori's analysis assigns a major role to the slave trade in the development of Africa's economic backwardness before 1850. In addition, Inikori has explored what he sees as the central role of diasporic Africans in the Americas during the Industrial Revolution in England, an argument first articulated in

Eric Williams's *Capitalism and Slavery* (1944). Inikori's various journal articles and conference papers have put forth the thesis that export markets throughout the Atlantic, markets generated through the labor of enslaved Africans, were crucial to the industrialization process in England. More than thirty years of scholarship culminated in the publication of *Africans and the Industrial Revolution in England: A Study in International Trade and Economic Development* (2002), a massive work drawing on classical trade theory and economic development analysis that focuses on the role of diasporic Africans in the Americas in fueling the growth of multilateral Atlantic trade between 1500 and 1850.

**INITIAL PUBLIC OFFERING (IPO)**

An initial public offering (IPO) is the first (“initial”) sale of equity to the public by a private company, usually through investment banks. The private company thereby becomes a public company (it “goes public”).

The purpose of an IPO is to raise a substantial amount of equity capital and create a public market for company shares to be traded on stock exchanges. The funds raised can be used to finance various projects, such as the expansion of manufacturing, marketing, and research and development (R&D) activities. If a company needs to raise a large sum that cannot be financed by private investors, such as venture capitalists or banks, then an IPO might be the best, albeit a costly, way to obtain the necessary funds (the pecking-order theory). The number of IPOs has fluctuated over time, but in some years, it has exceeded six hundred. According to Jay Ritter and Ivo Welch (2002), there were over six thousand IPOs during the 1980–2001 period, raising (in gross) $488 billion (in 2001 dollars). After the collapse of the dot.com bubble in 2000, the number of IPOs declined, but increased to 179 in 2004.

Once public, firms have direct access to the capital markets, enabling them to raise more capital by issuing additional stock in a secondary offering (a seasoned equity offering). Public companies can also more easily raise funds privately.

Some insiders participate in the IPO by selling part of their shareholdings to receive possibly a substantial amount of cash and to diversify their portfolios. This can also be an exit point for many venture capitalists. Insiders can also sell their shares at later dates to convert their equity into cash.

An IPO is an expensive way to finance in three aspects: (1) the fees and expenses; (2) the change in ownership structure; and (3) the disclosure requirements. The underwriting fees (underwriting discount or gross spread) alone in the United States amounted to 7 percent of the gross proceeds for 90 percent of the IPOs in the late 1990s, although the figures are lower in other countries (Chen and Ritter 2000). By going public, the previous owners (e.g., founders and venture capitalists) sell a slice of their company to dilute their ownership stake, which may reduce their ability to control the enterprise.

Firms must supply detailed information to the potential investors at the time of the IPO (in the registration statement, including a preliminary prospectus—commonly called a red herring—and the final prospectus). This requires costly preparation of reports, as well as possible disclosure of strategic and sensitive information to competitors. Subsequently, firms operating in the United States are required as public companies to file quarterly and annual reports with the Securities and Exchange Commission (less frequently in some countries).

Most IPOs are offered to the public through an underwriting syndicate, consisting of a number of underwriters who agree to purchase the shares from the issuer to sell to investors (best effort or firm commitment). The lead underwriter usually sets the basic terms and structure of the offering, including the allocation of the shares and the offering price. Syndicate members do not necessarily receive equal allocations of securities for sale to their clients. Most underwriters target institutional or wealthy investors in IPO allocations, since they are able to buy large blocks of IPO shares, assume the financial risk, and hold the investment for the long term. Since “hot” IPOs are in high demand, underwriters usually offer those shares to their most valued clients.

IPO companies tend to be young and small companies that lack a long-established record of profitable operation. The median age (from the year of founding) of IPO firms is seven years (Ritter 2006). Roughly one-third of IPO firms reported losses in their IPO prospectuses before going public, although being profitable used to be standard (Ritter and Welch 2002). Ritter (2006) reports that...
34.3 percent of IPOs are technology companies, of which 60.6 percent were backed by venture capitalists (compared to 39.9 percent of all IPO companies) for the 1980–2003 period. Therefore, investors purchasing stock in IPOs generally must be prepared to accept large risks for the possibility of large returns.

It is often observed that IPO shares open at a slightly higher price and close at a substantially higher price than the offering price at the end of the first day of trading (providing a significant return to the IPO participants with the allocated shares). This phenomenon is referred to as IPO underpricing or leaving money on the table and is observed not only in the United States, but also in other countries. A price run-up on the first day occurs when the demand exceeds the supply (the IPO is “hot” or the offering is underpriced).

The first-day return averaged 18.8 percent (the average daily market return is 0.05 percent) during the two decades prior to 2001. It decreased with the collapse of the bubble, but is still substantial at 12.1 percent. Although the first-day return is typically positive, IPOs have in general underperformed in the long run both in terms of stock returns and financial accounting results. Ritter and Welch (2002) report that the average three-year buy-and-hold returns (from the closing price of the first day) of IPOs underperformed by 23.4 percent (compared to the CRSP [Center for Research in Security Prices] value-weighted market index) and by 5.1 percent (compared to seasoned companies with the same market capitalization and book-to-market ratio). Smaller firms (in terms of sales prior to an IPO) appear to do much worse. Underpricing and poor long-run performance do not appear to be related in a systematic manner, however. Why do firms leave so much money on the table? Why do so many IPOs underperform? These questions are important subjects of academic inquiry in finance.

The academic accounting literature documents that many IPO firms engage in earnings management through an aggressive use of (discretionary) accruals to inflate reported earnings around the time of the IPO. Long-run underperformance is more pronounced for firms with more aggressive discretionary accruals (Teoh et al. 1998). Some IPO firms in R&D-intensive industries reduce R&D expenditures below the optimal level to increase reported earnings (Darrough and Rangan 2005). These findings suggest that some managers try and sometimes succeed to influence the perception of investors of IPO firms by manipulating accounting numbers.

**INITIATIVE**

An initiative (also known as a popular initiative) is a type of direct democracy (along with the referendum and the recall) in which citizens participate directly in governance, rather than indirectly by voting in elections. Initiatives allow citizens to propose a measure—either a statute or a constitutional amendment—by filing a petition with a specified number of valid signatures from registered voters. The measure is then subject to an up or down vote in the next election. The initiative is available in twenty-four states, about half of all U.S. cities, and in nations such as Ireland and Switzerland.

The initiative has existed in the United States since colonial times. It gained considerable popularity during the Progressive Era, when 83 percent of all states to adopt the initiative (20 of 24) did so between 1898 and 1918. Its emergence was closely tied to western populism, with 71 percent of initiative states (17 of 24) did so between 1898 and 1918. Its emergence was closely tied to western populism, with 71 percent of initiative states (17 of 24) lying west of the Mississippi River.

The initiative was called upon frequently in the 1910s and 1920s, but its use slipped into a period of relative dormancy during the Great Depression. It recaptured the public’s imagination again in 1978 with the passage of Proposition 13 in California, a controversial measure that cut the state’s property taxes in half. The political success of Proposition 13 spurred conservative interest groups and legislators to pursue tax-slashing measures in numerous other states, such as Oregon, Nevada, and Florida.

Proponents of initiatives argue that they provide a practical means for citizens to get results on issues that
their elected leaders fail to address. They also claim that initiatives help to educate citizens about public policy and the democratic process. Critics point out, however, that the initiative may empower special interests at the expense of the general public. While narrow economic interests rarely have the resources to mount successful initiative campaigns independently, well-organized citizens’ groups may be able win passage of new laws at the expense of minorities, the poor, and other disadvantaged populations.

Beyond their direct effects on public policy through the creation of new laws, initiatives have myriad indirect effects on citizens, interest groups, and political parties. For citizens, they help to stimulate voter turnout, cultivate civic engagement, and enhance trust in government. Interest groups may threaten to propose an initiative if the legislature does not do its bidding on a particular subject, thus enhancing the influence of such groups in policy matters. Political parties may invoke ballot initiatives as a means to achieve broader electoral objectives. For example, during the 2004 presidential election, Republican Party officials proposed initiatives banning same-sex marriage in critical swing states as part of an effort to promote voter turnout among conservatives sympathetic to President George W. Bush. Although survey evidence suggests that the marriage initiatives may not have had the effect that Republicans intended in 2004, their continued use in the 2006 midterm elections indicates that political parties now see polarizing ballot initiatives as a staple in their electoral strategies.

The debate over whether the initiative is beneficial or detrimental to democracy is unlikely to abate in the foreseeable future. While it is unclear which specific interests are most advantaged or disadvantaged by the initiative’s existence, it is clear that savvy political actors will continue to invent ways to co-opt initiatives to advance their goals.

**INPUT-OUTPUT MATRIX**

An input-output matrix, $A$, is a square table with elements $a_{ij}$ representing the amount of input $i$ required per unit of output $j$. A column of the matrix depicts the inputs needed for the production of a specific output and, therefore, can be considered a technique. The matrix is a constellation of techniques. For example, if $A = \begin{bmatrix} 0 & 1/3 \\ 1/2 & 0 \end{bmatrix}$, then the technique for product 1 is \( \begin{bmatrix} 0 \\ 1/2 \end{bmatrix} (1/2 a unit of input 2 per unit of output 1)$, while the technique for product 2 is \( \begin{bmatrix} 1/3 \\ 0 \end{bmatrix} (1/3 a unit of input 1 per unit of output 2)$.

If the list of inputs is complete, including factor inputs, the input-output matrix also contains “techniques” for the production of the factor services. In 1936, in the first input-output study, the Russian-born American economist Wasily Leontief (1906–1999) presented consumption coefficients for the “production” of labor services. This case is the so-called closed input-output model. If only produced inputs enter the input-output matrix, one speaks of the open input-output model.

The basic equation of the open model is the material balance, $x = Ax + y$, where $x$ is the vector of gross outputs, $Ax$ the vector of intermediate inputs, and $y$ is the vector of net outputs. The latter comprises the commodity components of household and government consumption, investment, and net exports. The material balance can be solved to determine the gross outputs, $x$, that are required to sustain the production of alternative bills of final demands, $y$. The solution is obtained by applying the so-called Leontief inverse, $(1 - A)^{-1} = 1 + A + A^2 + \ldots$, to the equation: $x = (1 - A)^{-1} y = y + Ay + A^2 y + \ldots$. The total output
equals the final demand itself plus the direct input requirements given by the input-output matrix plus the indirect requirements. For \( A = \begin{pmatrix} 0 & 1/3 \\ 1/2 & 0 \end{pmatrix} \), we have \((I - A)^{-1} = \begin{pmatrix} 1.2 & 0.4 \\ 0.6 & 1.2 \end{pmatrix}\). The first application was the U.S. World War II (1939–1945) effort.

The second equation of the open model is the financial balance, \( p = pA + v \), where \( p \) is the row vector of prices, \( pA \) the row vector of material unit costs, and \( v \) the row vector of value-added coefficients, representing the factor costs per unit of output of each product. The financial balance can be solved to trace the effects of changes in the factor costs (such as wages, rental rates, and taxes) on all the commodity prices. The solution is \( p = v + vA + vA^2 + \ldots \). Price equals unit factor costs plus the unit factor costs of the direct input requirements plus the unit factor costs of the indirect input requirements.

A simple but important application is the national income identity. Simple manipulation of the two equations yields the identity \( py = vx \). On the left-hand side is the value of the net output of the economy or the national product, and on the right-hand side is the value added generated in the production of the gross outputs or the national income. The identity between the national product and income cannot be disaggregated. For example, business services belong to intermediate demand, and hence do not constitute a component of the national product. Their production, however, contributes to national income. If one neglects that the national product must be based on the net output of the economy, one makes the mistake of double counting.

Roughly speaking, an input-output matrix details the average input requirements for the various products, and reductions in input-output coefficients represent productivity gains. The most important source of such reductions is technical change, but input-output coefficients may also be reduced by eliminating waste or by efficiency change. The third source of productivity growth is a composition effect. If relatively efficient firms gain market share, the input-output coefficients of the industry will fall.

Some confusion surrounds the dimensions of an input-output matrix. Some practitioners (including Leontief) consider these to be products, others consider them industries, and still others think of "sectors," a concept that supposedly integrates products and industries. To clarify, one must consider the statistical roots of an input-output matrix. These are an input matrix or use table \( U = (u)_{m \times n} \), and an output matrix or make table \( V = (v)_{m \times n} \). Here \( m \) is the number of products and \( n \) is the number of activities (firms or industries). The first column of the use table depicts the inputs of the first activity (typically agriculture) and the first column of the make table depicts the outputs of that activity. The question is how to construct an input-output matrix on the basis of an input and an output matrix.

The United Nations (1993) advocates the so-called commodity technology model. In the case of square tables (with an equal number of products and industries), this amounts to taking the product of the input matrix and the inverse of the output matrix. However natural, this construction is troublesome. A complication is that the consequent input-output matrix may have negative cells, due to the presence of secondary products. (The off-diagonal entries in the output table create negative elements in the inverse.) In the case of rectangular tables (with more firms than products), the commodity technology model stipulates that the input-output coefficients are the regression coefficients in the equation where the inputs are regressed on the outputs.

To circumvent the problem of negatives and to distinguish between average requirements and best practices, modern input-output analysis works directly with the input and output matrices, without constructing input-output matrices. The gross output variable, \( x_i \), is replaced by an activity vector, \( s \). (If the first component is 1.01, this means that agriculture produces an additional 1 percent.) In the material balance, intermediate demand, \( Ax \), is replaced by \( Ux \), and gross output \( x \) by \( Vs \). In short, by working directly with the input and output matrices one can calculate activity levels that sustain alternative bills of final demands without addressing the complications that surround the construction of an input-output matrix (ten Raa 2005).

The logic of input-output analysis can be extended from production to income distribution. Households consume products (the inputs) and provide factor services (the outputs). Social accounting matrices treat different types of households (e.g., rural and urban) as separate "industries." Just as a product row of a use table depicts the distribution of output across industries, a factor-income row of a social-accounting matrix depicts the distribution of factor incomes across households and other income institutions.

INSTITUTIONAL REVIEW BOARD
In the United States, all academic institutions and other entities that receive federal government funding and that conduct research involving human subjects must maintain an institutional review board (also known as an internal review board, or IRB) to oversee the adherence to federal regulations that govern research using human subjects. These boards are committees of professional researchers and administrators who screen research proposals with the intent of enforcing the federal regulations covering research on human subjects. The primary intent of these regulations is to protect human subjects from potential physical or mental harm that may result from participating in a research project.

All research projects that employ human subjects, from medical drug trials to social behavior surveys, must be reviewed by the host institution’s IRB to ensure that federal regulations are met within the proposed research design. Before proceeding with a project, researchers must receive approval, or in some special cases an exemption, from their local IRB. All research projects involving human subjects or employing data collected from people are subject to federal regulations, regardless of the source of financial support for the project. Since institutions found violating human subject regulations may be forced to forfeit all federal funding, the IRB is a critical component of any research university’s governance structure.

HISTORICAL BACKGROUND
The global movement to safeguard and protect human subjects can be traced back to the aftermath of World War II (1939–1945) and the war trials held in Nuremberg, Germany, when the world learned of the atrocious medical experiments conducted on prisoners interned in Nazi concentration camps. The Allies developed what came to be known as the Nuremberg Code to assist the military tribunal in judging the Nazis’ conduct. This code outlined the basic tenets that became the foundation of the ethics that govern research on human subjects. From the subjects’ perspective, these tenets include: (1) the ability to voluntarily participate or withdraw from participation; (2) the freedom from coercion to participate; and (3) the right to be informed of all potential risks and benefits of participation. Furthermore, the code’s provisions require that researchers be professionally qualified for the specific type of research in question, that they use appropriate research designs, and that they seek to minimize the risk of potential harm to human subjects.

Throughout the 1950s and 1960s, numerous medical associations and national governments around the world passed declarations and endorsements of professional codes of conduct based on the Nuremberg Code. In the United States, this occurred when the National Institutes of Health issued its Policies for the Protection of Human Subjects in 1966. In 1974 the Department of Health, Education, and Welfare raised these policies to regulatory status and introduced IRBs as a mechanism for institutions to ensure the protection of human subjects through regulatory compliance.

The American codification of rules designed to protect human subjects in the 1960s and 1970s was spurred on by two high-profile cases that employed procedures that many considered to be unethical. In 1963 Yale psychologist Stanley Milgram (1933–1984) published the results of a study on obedience to authority in which one human subject was asked to deliver electrical shocks of increasing voltage to another person who was secretly collaborating with the experimenter. Even though the shocks were fictitious, the screams and pleas of the collaborator led the subject to believe that they were real. Ironically, Milgram’s motivation for the study was the psychology behind the Nazi atrocities. In 1972 the press revealed that the U.S. Public Health Service was conducting a decades-long clinical study of the effects of syphilis using a sample of several hundred, mostly poor, African Americans living near Tuskegee, Alabama. While some subjects were given proper treatment, others were not informed of their diagnosis and were prevented from receiving treatment from other health-care providers. The primary goal of the Tuskegee study was to determine how, over extended periods of time, syphilis affects the human body and eventually kills. Not only did many human subjects in this experiment die from nontreatment, but the disease was also spread to the spouses and children of the untreated participants. The Tuskegee researchers did not receive the informed consent of the subjects and did not disclose the risks of participation to them and their families. Once it became public, the study was terminated and the remaining subjects were given proper medical care. Eventually, in 1997, President Bill Clinton issued a formal apology on behalf of the U.S. government.

The passage of the National Research Act (1974) established the National Commission for the Protection of Human Subjects of Biomedical and Behavioral
Research. This commission’s 1979 report, commonly referred to as the Belmont Report (named after the Smithsonian Institution’s Belmont Conference Center, where the commission met) served as the basis for the subsequent revisions to the federal regulations, which eventually evolved into the current Federal Policy for the Protection of Human Subjects (Code of Federal Regulations, Title 45, Part 46). As of 2005, sixteen federal departments and agencies that support or conduct human subjects research had adopted this policy, which is sometimes called the Common Rule.

REGULATORY PRINCIPLES AND PRACTICES

Three general ethical principles outlined in the Belmont Report serve as the basis for the rules outlined in the Common Rule: (1) respect—honor for the personal dignity, autonomy, and the right to privacy of individuals; (2) beneficence—the obligation to minimize the risks of potential harm to human subjects while seeking to maximize the benefits of research to humanity; and (3) justice—ensuring that the benefits and costs of research on human subjects are distributed equitably. These principles guide the regulatory rules overseen by IRBs in the daily practice of academic research. For example, the requirement to obtain informed consent is derived from the principle of respect; the requirement to explicitly weigh potential risks against potential benefits is derived from the principle of beneficence; and the requirement to recruit human subjects fairly is derived from the principle of justice.

For an experimental project involving human subjects to fall under the regulations of the Common Rule, it must be classified as research. Specifically, the Common Rule defines research as “a systematic investigation, including research development, testing and evaluation, designed to develop or contribute to generalizable knowledge.” Projects that fail to meet this definition of research are exempt from the regulations. In some cases, local IRBs have exempted whole classes of academic exercises, most notably oral history projects, from their oversight. However, individual researchers are not at liberty to make an exemption determination on their own; only an IRB is allowed to review a proposed project and to determine if it meets the Common Rule’s definition of research.

The technological revolution of the late twentieth and early twenty-first centuries spawned a resurgence in advocacy for the protection of privacy and individual rights. This was a contributing factor to what some saw as a tightened enforcement of Common Rule regulations by local IRBs, which were also being forced to respond to several high-profile cases of careless procedures during medical drug trials. As a result, many social scientists and educators discovered that their institutions wanted to make a closer examination of their research practices and procedures. The additional scrutiny and accompanying paperwork resulted in public complaints about the regulatory burdens imposed by the IRB system.

Some social scientists claim that the human subjects regulations are overly burdensome and have a stifling effect on the research climate. They say this is particularly true for survey-based research projects where the potential for personal harm to human subjects is either negligible or nonexistent. To date there is little compelling empirical evidence that the IRB system has significantly reduced the level of research using human subjects. However, most social scientists will agree that the enforcement of Common Rule regulations by IRBs does protect human subjects from highly risky experimental research practices. Given this, it is likely that the IRB system will remain entrenched in the governance of American academic research institutions for the foreseeable future.

INSTITUTIONALISM

The institutional approach to the economy had its genesis in the work of Thorstein Veblen, whose *The Theory of the Leisure Class* (1899) introduced the term conspicuous consumption into popular lexicon. A defining characteristic of Veblen’s approach was the dichotomy between the dynamic forces of technology and the static forces of institutions. This conflict was played out in a modern business economy where the technological potential to produce goods was impeded by the demand of business enterprise that goods be sold profitably.

The terms institutionalism and institutional economics were coined in 1919 by Walton Hamilton. In an article in the *American Economic Review*, he presented the case that institutional economics was economic theory. This was true, Hamilton argued, because only institutional economics provided a unified approach to economic problems. Further, it rejected a laissez-faire view of the world and emphasized the role of institutions and the process of economic change. Finally, institutional economics understood the importance of habit and rejected the “pleasure and pain” of the utilitarian view of human behavior. For the next decade and a half, institutionalism gained important adherents in academia, many of whom subsequently rose to prominent policymaking positions in government.

As Yuval Yonay documented in *The Struggle over the Soul of Economics* (1998), institutional economics was on the rise in the interwar period and appeared poised to be a significant force in American economics. There were the labor studies of John R. Commons and his students at the University of Wisconsin. Veblen’s student, Wesley Clair Mitchell, was the first director of the National Bureau of Economic Research. His pioneering work on business cycles was based on Veblen’s *The Theory of Business Enterprise* (1904). Mitchell’s student, Simon Kuznets, was instrumental in developing national income accounting. Yet another institutionalist, Morris Copeland, a student of J. M. Clark’s, developed the flow of funds accounting, which in the 2000s is regularly reported by the Federal Reserve System and links the financial balance sheet with national income accounting.

Idle machines and hungry people in the 1930s were a glaring illustration of the conflict between making money and making goods. Many important institutionalists such as Rexford Guy Tugwell, an original member of Roosevelt’s Brain Trust, were involved in the economic policy changes of the New Deal era. Adolf Berle and Gardiner Means, whose *The Modern Corporation and Private Property* (1932) had provided an understanding of the implications of the separation of ownership and control in the modern firm, were also institutionalists in the administration.

THE TEXAS SCHOOL

The most significant concentration of institutional economists in the United States in the post-World War II period, other than Commons’ Wisconsin school of institutionalism, was at the University of Texas (UT) at Austin. The leading figure in the Texas School was Clarence Edwin Ayres, a philosopher turned economist who was greatly influenced by Veblen and John Dewey. The department included other figures who shared a common methodological tool (the Veblenian dichotomy) and were in agreement on economic policy; each was a strong personality, and collectively they sought to disseminate their view of the world. Though the institutionalist tradition remained at UT until the 1980s, the peak period of influence was undoubtedly in the 1950s. Another war, this time the U.S. intervention in Vietnam, divided the department and hastened the demise of institutionalism at UT.

OUT WITH THE OLD, IN WITH THE NEW

Some have viewed institutionalism as a story outside the mainstream of economics. However, as Yonay showed, the story of the rise and fall of institutionalism is intricately tied with changes in society and the evolution of the mainstream of economics. Just as the changes of World War I and the Russian Revolution provided a context for the rise of institutionalism, it was the aftermath of the Great Depression and World War II that resulted in its decline. Within the economics profession, institutionalism was swept away by mathematics, econometrics, and Keynesian economics. By 1956 a roundtable at the annual meetings of the American Economic Association pronounced the end of institutionalism. For the next three decades, institutionalism existed in the underworld of economics. Institutionalists were pushed toward, or willingly embraced, the view that they were outside the mainstream. This tended to marginalize the institutional economists that followed Veblen.

In 1985 Martin Bronfenbrenner published an article in the *American Economic Review (AER)* in which he stated that institutionalism had been pushed into “minority status although not into complete obscurity” (Bronfenbrenner 1985, p. 20). Attempts to respond to Bronfenbrenner were rebuffed by the editors of the *AER*. It was not until 1998 that there was again an AEA session on institutionalism, but this time it was the “new” institutionalism of Ronald Coase, Douglas North, and Oliver Williamson. This also rekindled an interest in the “original” institutional economics. The editors of the *Journal of Economic Literature* invited a paper on the institutional economics of Veblen and Commons.

The relationship between old and new institutionalism is an uneasy one. On the one hand, many of the new
institutionalists view the Veblen-Commons-Ayres tradition to be one that is anti-theory—meaning anti-neoclassical theory. On the other hand, the old institutionalists view the new institutionalism as still wedded to outmoded views of technological change, human behavior, and the market mechanism. Despite differences that some see as significant, there is little doubt that the new institutionalism represents a recognition of the limitations of textbook economics and the validity of the concerns raised by Veblen and his followers.

THE IMPACT OF INSTITUTIONALISM

If one considers Hamilton’s 1919 definition of institutional economics, it seems evident that the mainstream of economics has come a long way toward becoming institutional economics. This evolution has occurred mostly without the direct input of original institutional economists. The mainstream has sought a unified explanation through the microeconomic foundations of macroeconomics. Today neoclassical economics has recognized through the analysis of noncompetitive market structures that perfect competition does not prevail. Even the theory of contestable markets is a move beyond the stale concept of perfect competition. Virtually all economists now accept that institutions matter. Neoclassical economics has developed sophisticated economic dynamics and evolutionary game theory. The work of Herbert Simon on satisficing and bounded rationality is a recognition that the atomistic, hedonistic man of neoclassical economics is not valid, and instead humans, though they may seek their own self-interest, are constrained from doing so precisely because they have limited capacity for rational behavior.

Though there is a basic similarity between the old and the new institutionalism, the essential difference hinges on whether one believes that there is an invisible hand that guides the creation of efficient institutions or whether it is all a matter of habit, technological change, and path dependency. The new institutionalists tend to emphasize the progressive aspects of institutions, while the old institutionalists see institutions as holding back technology. A balance between these views would seem to be the most realistic view of how society evolves over time.

As Ron Stanfield explained, the bottom line is that economics has advanced. It is becoming more realistic in the face of technological and institutional change in society (Stanfield 1999, pp. 252–253). It would seem that there is now a real possibility that Hamilton’s claim will be realized in the twenty-first century: institutional economics is economic theory.

INSTRUMENTAL VARIABLES REGRESSION

In regression analysis social scientists use data to understand relationships among the people, institutions, and conditions represented by the measurements contained in the data’s variables. These observations of the variables, along with some assumptions about the relationships, are used to test hypotheses generated by the model. The method of instrumental variables (IV) estimation addresses a particular difficulty encountered in ordinary least squares (OLS) regression: One or more of our explanatory variables may be “endogenous.” Consider either the simple regression model with observations $i = 1, \ldots, n$, of variables $x$ and $y$.

\[
y_i = \beta_0 + \beta_1 x_i + \epsilon_i ,
\]

or the multiple regression model analogue with additional explanatory variables (without loss of generality, one additional variable)

\[
y_i = \beta_0 + \beta_1 x_{1,i} + \beta_2 x_{2,i} + \epsilon_i .
\]

The goal of regression analysis (using OLS, IV, or other methods) is to estimate the values of the $\beta$ parameters and thus the relationship between $x$ and $y$ and, in the process, calculate values for each observation’s error, $\epsilon_i$, as well. IV estimation can improve our interpretation of this
relationship as causation rather than simply correlation. IV estimation attempts to address the concern that correlation between $x$ and $\varepsilon$ confounds the causation running from $x$ to $y$. There are several reasons to suspect this “endogeneity,” the correlation between the error and an explanatory variable.

First, the explanatory variable(s) and the dependent variable may be determined simultaneously—there may be feedback from the dependent variable to the explanatory variable. For example, when estimating the demand curve, $x$ is a good's price, and $y$ is the quantity of that good purchased. The observed quantity is an equilibrium quantity, which is jointly determined with price. Higher prices are associated with larger error terms. Due to the law of supply, a deviation of price above the demand curve induces a deviation of quantity to the right of the demand curve, which would bias OLS regression to measure a weaker relationship than actually exists. In fact the earliest known application of IV estimation was Philip Wright's (1928) study of the butter and flaxseed markets.

Second, there may be an omitted variable that is correlated with both the explanatory and explained variables. IV methods are often associated with labor economics, where the return to education may be of interest: the effect of another year of education ($x$) on a person's future earnings ($y$). Ability is an omitted variable in this regression—either because it is unmeasured or because it is difficult to measure accurately. The estimate of $\beta$ may be biased if individuals who are more likely to pursue additional education also have more innate ability that is rewarded in the labor market by higher wages. The correlation between education on wages calculated by OLS would be larger than the correlation holding ability constant.

Third, an explanatory variable may be measured with error. Because an explanatory variable’s ($x$'s) measurement error is part of the regression’s unobserved error ($\varepsilon$), larger errors are associated with larger values of the explanatory variable, and thus $x$ is endogenous. The importance of this bias will be affected by the size of the measurement errors relative to other error components.

Although Wright (1928) is recognized as the first appearance of the method of instrumental variables, there is some controversy as to the actual author of the technique—it may have been Philip Wright’s son Sewall. James Stock and Francesco Trebbi (2003) confirm that Philip deserves the credit. Olav Reiersøl (1941) was the first to use the term *instrumental variables* when the method was “rediscovered” decades after the Wrights did their work (Reiersøl 1945; Geary 1949). The Cowles Commission (Christ 1994) and Trygve Haavelmo (1944) pursued issues of model identification, to which IV techniques are linked. The development of two-stage least squares (Theil 1953; Basmann 1957; Theil 1958) was an important step in computational feasibility and statistical efficiency for equations with multiple endogenous variables and instruments. In the early twenty-first century the discussion of instrumental variable estimation’s merits and faults continues (Angrist and Krueger 2001; Rosenzweig and Wolpin 2000), even in the popular press (Hilsenrath 2005; Whitehouse 2007).

**REGRESSION TECHNIQUES**

OLS regression estimates $\beta$ in equation (1) by calculating the covariance of each side of the equation with $x$. Taking that covariance on each side of (1) produces the equation

$$\text{cov}(x, y) = \beta \text{cov}(x, x) + \text{cov}(x, \varepsilon). \quad (3)$$

If $x$ and $\varepsilon$ are uncorrelated, so that $\text{cov}(x, \varepsilon) = 0$, then we can estimate $\beta = \text{cov}(x, y) / \text{cov}(x, x)$ from (3), and this also produces estimates of each observation’s $\varepsilon_i$. Without the population-level assumption of zero correlation between the explanatory variable and the equation errors, we do not have enough information to “identify” both the $\beta$ and $\varepsilon_i$ values.

IV regression addresses the problem of $\text{cov}(x, \varepsilon) \neq 0$ by assuming that the correlation between $\varepsilon$ and another variable $z$, the “instrumental variable,” is zero: $\text{cov}(z, \varepsilon) = 0$. Taking the covariance between this instrumental variable and our equation (1) (replacing $x$ in the first terms of equation (3)) produces

$$\text{cov}(z, y) = \beta \text{cov}(z, x) + \text{cov}(z, \varepsilon)$$

which can be solved for $\beta = \text{cov}(z, y) / \text{cov}(z, x)$, as long as $\text{cov}(z, \varepsilon) = 0$. Note that we do not replace $x$ entirely in the equation; we are still investigating the relationship between $x$ and $y$, not that between $z$ and $x$. In fact the condition that $z$ and $\varepsilon$ be uncorrelated implies that there is no relationship between $z$ and $y$ other than through the relationship between $z$ and $x$. This solution for $\beta$ also shows mathematically why it is important that $\text{cov}(z, x) \neq 0$.

The two important assumptions of IV are reflected by the connection between the instrument(s) $z$ and $x$ and the lack of any other connection between the instrument(s) and the dependent variable. The first assumption can be checked: The instrumental variable $z$ must be correlated with the endogenous explanatory variable $x$. The second assumption relies on our knowledge of the social phenomenon under study. The only effect of the instrument $z$ on the dependent variable $y$ is through the explanatory variable $x$, so that there is no correlation between the instrument and the error $\varepsilon$ in equation (1). Because we do not actually know the true value of the error, we cannot fully test this second assumption. Although we can test the first assumption statistically, it too should be supported by our understanding of the
underlying theory and relationships. Finally, IV estimates are consistent but biased, which indicates that large samples are necessary.

Using multiple regression to estimate equation (2) requires calculation of a column vector β. Each observation can now be expressed as a row vector, resulting in the matrix X containing all observations’ explanatory variables and the column vector Y containing all observations’ dependent variable, $Y = X \beta + \varepsilon$. OLS calculates β as $(X' X)^{-1} X' Y$, again requiring zero correlation between the error ε and any of the explanatory x variables. The IV method instead calculates $\hat{\beta}$ using a row vector of instrumental variables, collected over all estimates in the matrix $Z$, as $(Z' X)^{-1} Z' Y$.

Returning to the examples, instrumental variables addresses each of them as follows. First, in the estimation of a demand curve, an instrument (z) for price is the cost of production: It is correlated with the price that buyers pay (x), but it is not correlated with quantity demanded (y). Second, a particularly well-known instrument for years of education is Joshua Angrist and Alan Krueger’s (1991) quarter of birth, which is explained in more detail below. Quarter of birth is unlikely to have a direct effect on future earnings, but if a child is born close to the cut-off date, he or she will start school either substantially earlier or substantially later than other children but will still be required to remain in school through age sixteen. Thus children are required to have up to one year of additional education. Third, if the dependent variable is measured with error, we can use another measure of the dependent variable as an instrument, so long as the two measures’ errors are not correlated.

The method most often used to implement IV is two-stage least squares (2SLS); it efficiently takes advantage of multiple instruments in addition to multiple explanatory variables (both endogenous and exogenous), as in equation (2). We can use the relative efficiency of IV over OLS to test for endogeneity with a Hausman (1978) test, and we can use “extra” instrumental variables to test their exogeneity.

**SHORTCOMINGS OF THE INSTRUMENTAL VARIABLES METHOD**

Before considering the drawbacks to the instrumental variables method, note that we are only concerned with the issue of endogenous variables if causality is an important part of the analysis. If the goal is only to describe statistical relationships in the data, IV estimation is not necessary (Moffitt 2003a).

We could also imagine that the omitted variable bias could be addressed by choosing participants randomly, avoiding the need to use IV methods, yet this is typically difficult in the social sciences. Although there have been some innovative public policy experiments (Moffitt 2003b) and field experiments (Smith 2002), many important questions in the social sciences require natural experiment methods, of which IV is an important part.

An important drawback to the method of instrumental variables is low correlation between the instrument(s) and an endogenous variable. The explanatory power of the regression is limited as a result. Not only are standard errors large, but a lack of variation in the instrument will translate into a limit on the range of behaviors that we can understand from the IV regression. We can return once more to our three categories of endogeneity and their associated examples. First, we learn about the demand curve only to the extent that changes in the supply curve reveal it. The portions of the demand curve that are not explored by changes in supply are no longer part of the estimation. Second, Angrist and Krueger (1991) estimated the return to education by instrumenting for education by quarter of birth. The combination of compulsory starting dates and compulsory schooling through the age of sixteen means that students born in different seasons may have up to a year’s difference in compulsory education. Yet when instrumenting years of education by birth date, the regression estimate now has little relevance to those students who continue on to college, for example, because entrance to college is not determined by age but by high school graduation and performance in high school. Compulsory schooling does not affect the education decision of these people. Third, errors in measurement require an alternate measurement technique that covers a range of values similar to the measurement technique of interest.

Various authors also highlight the lack of specific theory in many instrumental variable studies. Mark Rosenzweig and Kenneth Wolpin (2000) carefully review many results from the labor economics literature, describing the theoretical assumptions implied by those studies’ use of IV estimation. They argue that implicit assumptions are made whether the practitioners employing IV realize it or not. In either case, what these critiques call for is an improved understanding of the people, institutions, and conditions that are interacting as we study them. With better understanding we can improve our ability to generate relevant testable hypotheses about the actors’ decisions and their connections to the conditions and institutions they face.

INSURANCE

Risk is ubiquitous in the world and is generally considered a burden. Risk management, the art of coping with this onus, takes several forms: (1) doing nothing, or bearing the burden; (2) avoiding the risk, which includes reducing or quitting the risky activity; (3) spending resources to reduce the risk’s implication or probability, such as self-insurance; (4) hedging; and (5) transferring the burden to someone else, which is insurance. Some risks, like individual and group extinction, are so important that one could study history as the theme of risk management or view culture and social institutions like marriage and state, as evolving in response to the challenge of risks. Risk management is not special to humans—for example, ants spend effort and hoard excessive food, a form of self-insurance that humans parallel by precautionary saving—but insurance is a human invention.

Insurance is a transaction that transfers a specified risk to another party for a fee, called a “premium.” In return the insurer provides the insured with a promise of indemnification (insurance company payment for damages) should the specified event occur. The specified events vary widely and comprise the different lines of the insurance industry: marine, property, vehicle, liability, life, and health, but the basic structure is the same. The amount of indemnification may be event-dependent (small or large fire) or fixed (life). In life insurance the event specified is either death or longevity. Insurance is both a consumption good consumed by households and an intermediate input purchased by firms. In property insurance the business is split about equally between households and firms. As can be gleaned from a cross-section as in Table 1, insurance is growing faster than national product, suggesting that it is a luxury good (income elasticity larger than one) and a “super normal” input. It may imply that adequate development of the insurance industry is vital for economic development and growth. By providing assets whose value is contingent on a given random state of nature, insurance helps make the market more complete and therefore more efficient. Without insurance availability some useful transactions and investments would be curtailed or thwarted.
The demand for insurance is theoretically explained by risk aversion. A risk-averse person faced with a probability $p$ of loss $D$, like a house that may burn, is willing to insure against that risk even at a premium higher than the mean damage $pD$. Firms demand insurance to placate their risk-averse owners and other parties, like customers, suppliers, employees, and lenders, thereby securing better contract terms with them.

Insurance differs from gambling by some of its fundamentals designed to restrain devious incentives. The purchaser must have “insurable interest,” that is interest in the well-being of the insured asset (owner, mortgage lender). Other than in the case of life insurance, indemnification must be bounded by the value of the asset, including by double coverage. In return for indemnification, the insured surrenders to the insurer subrogation of all his relevant legal rights to claim from other parties. Still, the insurance market is burdened by fraud and by imperfections like adverse selection, where the firm cannot completely ascertain the risk of each customer thereby charging a premium that attracts the bad risks more than the good, and by moral hazard, where after the insurance transaction the insured may wish to increase his or her risk.

The supply side raises two puzzles. First, what is the relative advantage of the insurer in bearing risks over its clients? Second, if indeed it has some such relative advantage, why does it seek to insure itself by purchasing reinsurance? Reinsurance is a transaction where an insurer buys insurance from another insurer thereby transferring, or ceding, some of its risks and business to others. The remainder is called retention. Reinsurance is a global industry with some large specialized firms.

The production of insurance can be done in two distinct modes: mutual and capital-backed. A mutual is an association of members-customers who barter in insurance and pledge to indemnify each other if damaged. This insurance is backed by members’ commitments and capital. It must be a natural and intuitive arrangement since it goes back to antiquity. Second-century CE agreements among boat or donkey owners are legally analyzed in the Talmud.

Even a two-person mutual is advantageous. If each one has total property $W$ and faces an independent risk of losing value $D$ (like a house by fire) with probability $p$ the advantage of such a mutual is:

$$[p^2U(W - D) + 2p(1 - p)U(W - D2) + (1 - p)^2 U(W)] - pU(W - D) + (1 - p)U(W)$$

$$p[1 - p][U(W - D2) - U(W - D1)] - [U(W) - U(W - D2)] > 0$$

The first line in (1) is the expected utility of each person in the 2-member fire-mutual, while the second line is his expected utility bearing the risk alone. The inequality follows from the concavity of the utility function that is implied by risk aversion.

The agreement improves with any additional member. The attractiveness of an $n$-member mutual may be explained by the expediency of (risky) portfolio diversification. Instead of holding one risky asset valued $D$, the agreement affords the member to hold the risk of $n$ small assets, each valued $D/n$, which is always better for a risk-averse. In (1) the two fire events were assumed independent. Partial positive dependence leaves the inequality intact but reduces the advantage. Most mutuals collect a provisionary premium upfront and reassess members after risks’ realization, collecting more or refunding some.

However the main mode of insurance provision nowadays is by a stock company where insurance is backed by equity capital. Such production dates to the fourteenth-century marine transaction that combined banking and insurance. In such maritime loans the lender would finance a trade transaction but waive the loan if the vessel is lost. It appeared in two variants regarding the collateral: bottomry (the vessel) and respondentia (the cargo). While in a mutual the number of owners-partners must vary jointly with that of the insureds, in the stock firm the two are independent.

**OPERATION**

Assume schematically an insurance firm that sells only one type of policy against the risk of, say, fire, which occurs independently with the same known probability $p$ of total loss $D$ for each customer. Let $V$ be the firm’s capital before any insurance transaction, serving as a cushion to enhance the value of its policies-promises. Suppose $n$ such policies are sold at price $s + c$ where $cn$ covers the cost of running the business. Usually $s$ would exceed $pD$, the expected loss (and indemnification), and the balance is a safety factor that goes to profit and tax. The revenue $ns$ is called unearned reserve because it is designated for probable coming claims. As time elapses the uncertainty regarding the year’s fires is gradually cleared, more and more of the reserve becomes earned reserve, owned by the firm and part of its annual profit and of $V$. The firm’s funds $V + ns$ are meanwhile invested and bear a random rate of return.

r thereby generating a major part of its profits. The number of fires that occur is a random variable k. If the two random variables happen to have realizations R and K, then the firm’s net worth at the year end is \((V + ns)(1 + R) - KD\). If it is negative, the firm’s future promises are worthless so it is declared insolvent and ceases operation.

The risk of failure is real and troubling. In the United States during the 1990s approximately 70 firms, or 0.8 percent of all insurance firms, failed within a year. The condition \((V + ns)(1 + r) - KD < 0\) points out the reasons for failure: low V; low premia \(s\); low \(R\); large \(K\). The dependence of the ex-ante probability of failure \(\text{Prob}((V + ns)(1 + r) - KD < 0)\) on the magnitude of \(n\) is less clear-cut. Conventional wisdom attributes the relative advantage of the stock insurance firm in bearing risk to the multitude of clients and the law of large numbers. However, whether the numbers \((n)\) in insurance are large enough to warrant this explanation is an empirical question. According to the 1963 work of Paul A. Samuelson, the advantage of the insurance firm lies in the multitude of its owners. Spreading a given risk over many bearing shoulders (stockholders) tends to evaporate its burden. In 1970 Kenneth J. Arrow and Robert C. Lind analyzed a large risky public project, where the risk was spread over the population, and demonstrated it for a single risk. This result explains the advantage that governments may have in insuring against catastrophic losses. It does not address the issue faced by the insurance industry of insuring against multiple risks. In this light, reinsurability is a handy mechanism to spread risks.

BUSINESS CYCLE

The insurance industry manifests a peculiar business cycle of its own. In times of hard market, prices are high and yet insurance is hard to get as firms offer only constrained extent of coverage and carefully select the clients. The result is high profits and rise in surpluses. That by itself may lead to the opposite, soft market, as the high surplus warrants more business and risk taking so prices go down to attract more and necessarily lower-grade customers. Profits go down, equities are depleted, and the cycle repeats itself.

INNOVATIONS

Since the 1990s a rise in world catastrophes like earthquakes, hurricanes, and terrorist activities drained world insurance surplus and constrained the industry’s production capacity. In response financial innovations were introduced as substitutes for equity capital. The simplest is catastrophe bonds. An insurer issues such a bond, and the repayment of the interest and/or the principal is made contingent on a specified event like the catastrophe cost (for the insurer, for the region, or for the world) not exceeding a predetermined number. It shifts some of the risk from shareholders to bond holders and is a modern resurrection of the Middle Ages’ maritime loan-cum-insurance. More complicated instruments are call and put options whose strike price is some catastrophe number.

REGULATION

All over the world, insurance industries are regulated. The raison d’être of regulation is the risk of insurers’ insolvency. Such occurrence would disrupt the economy, prevent gains from trade in risk-bearing, and cause personal loss and suffering to consumers. Although insurers themselves would suffer in case of insolvency, they can not be fully counted on to take steps to avoid it because of several market imperfections. First, because of the limited liability of a stock company, stockholders would not have to bear, in case of insolvency, its full cost but lose at most their equity. That weakens stockholders’ incentives to avoid excessive risk. Second, moral hazard and agency problems develop. After issuing policies purchased under presentation of a certain risk level, the insurer may wish to assume more risk because part of its cost is borne by the insured policyholders. Regulators issue guidelines regarding the extent of underwriting, prices, and investment policy. They monitor the business and upon detecting signs of trouble intervene by issuing various directives.

INSURANCE INDUSTRY

Contracts transferring risk have been in existence since at least the time of ancient Babylon. The growth of a large-scale insurance industry dedicated to regularizing and facilitating transactions dates, however, from the growth...
of transoceanic shipping in the seventeenth century as well as the growth of mathematical and computational sophistication needed to support mass transfers of risk. The industry has grown to one of the world’s largest and in the twenty-first century comprises a ubiquitous and central component of life in developed nations, with written premiums surpassing $3.4 trillion in 2005.

Insurance—as a contract that often overcomes impediments to trade created by risk and that, of necessity, often requires significant agglomerations of corporate wealth—has long been an instrument of social success and social disgrace. It has unquestionably permitted the development of modern capitalism by stabilizing large concentrations of property or, in the case of life insurance, the preservation of family wealth with reduced regard for the longevity of particular family members. On the other hand, it was critical to the development of industrial-era slavery by permitting those involved in human trafficking to diversify the significant risks involved. It has often fueled and ameliorated the planet’s environmental woes by permitting various industries to thrive notwithstanding the oft-materializing risk of environmental harm they create, though it has also provided a major source of capital from which those injuries can be at least partly redressed. It has increased safety in fields such as fire prevention, building codes, and vehicle safety by providing a relatively centralized repository of information on risk and significant motivation for its reduction. And it has unquestionably transformed the legal system in many jurisdictions by providing otherwise unavailable large sources of wealth to vindicate rights formally created by those jurisdictions.

The modern insurance industry is divided into three parts: (1) a life and health insurance segment; (2) a property/casualty segment; and (3) a financial management segment involving reinsurance and various forms of excess insurance. While many companies engage in all parts of the industry, often through various subsidiaries, others specialize in only segments and subsegments of the market consistent with their skills in marketing, assessing risks, processing claims, and coping with regulatory impediments. The life and health industry generally assesses the health trajectories of prospective insureds. Private health insurance is used in the United States to defray the significant cost of medicine and is often (though decreasingly) offered by employers as a tax-advantaged prerequisite. It also frequently serves there as a buying agent, negotiating in advance for lower prices for medical services on behalf of its insureds. In nations with broader government-provided health care, health insurance nonetheless often functions as a supplemental vehicle for transferring the risk associated with procedures the government plan does not cover or as to which government-provided care is thought inadequate. Life insurance offers payment to reduce the risk of premature death or, in the case of annuities, offers a stream of income to offset the risk of living longer than expected. It also frequently permits a tax-advantaged form of investment.

The property and casualty insurance insures individuals and businesses from direct and indirect losses due to fire, various forms of natural disaster, and other “perils.” Casualty insurance transfers the risk of the insured encountering various legal obligations, such as an obligation to pay damages in a lawsuit or to perform on a contract. Major forms of casualty insurance include liability insurance, suretyships, and marine insurance. Large segments of the legal services industry assist casualty insurers in defense of claims against their insureds.

ECONOMIC CHALLENGES

Much of the modern insurance contract represents an effort to address four economic challenges inherent in virtually any attempt to transfer risk. Reducing this process into words often makes many insurance contracts extremely complex and forbidding documents, as insurers use various shorthands and jargon to compress complex concepts. The first challenge, moral hazard, is the proclivity of people with insurance to increase the level of insured risk they encounter beyond what otherwise would be the case. Insurers control moral hazard through such means as making the insurance incomplete through deductibles that reduce by a fixed or formula amount an insurer’s otherwise obligation to pay a claim. The insurer likewise controls moral hazard through various exclusions and conditions that limit its obligations unless the insured adheres to various behavioral norms thought to reduce risk. These control mechanisms may make contract administration more costly, however, and can lead to dispute when the provisions involved are ambiguous or surprising to the insured.

The second challenge, adverse selection, is the proclivity of insureds that accurately perceive themselves as having a higher risk of loss than would be imagined by the insurer to purchase insurance disproportionately. Insurers attempt to curb adverse selection through tighter “underwriting,” the examination of prospective insureds before contract formation is complete, through insistence on legal systems that condition the insurer’s payment obligations on various forms of information transfer from insured to insurer, and through conditions and exclusions that prevent risk transfer in situations where the information needed by the insurer or the proper interpretation of that information would prove too costly for the particular insurer. Adverse selection potentially poses great hazards to the insurance industry, particularly where prospective insureds harbor secret information about their own level of risk. Various insurance systems have entered “death spirals” when they were unable to control adverse selection.
A third issue is that of systematic risk. Insurance works best when the risks are independent of one another and insurers can thus depend on the unbreakable “law of large numbers” to assure their profitability. When insurers encounter correlated risks, such as those posed when insuring a large number of homes in an area of seismic activity or hurricane risk or, potentially, terrorism risk, they thus either enter the market only with great caution or deploy various risk spreading and aggregation mechanisms such as reinsurance or catastrophe bonds that reduce systematic risk. These mechanisms are capable of succeeding because, while the risk that a home in the vicinity of one volcano will be destroyed from an eruption is correlated with destruction to a neighboring home, an insurance system that pooled both of their risks with those of homeowners near other seismically uncorrelated volcanoes would effectively create somewhat larger but still uncorrelated risks as to which the law of large numbers would more closely apply. The increased globalization of the insurance industry, coupled with the growth of institutions such as reinsurance, has greatly assisted with this problem.

Finally, there is simply the matter of insurers keeping their promises. Particularly in cases of life insurance or various “toxic tort” claims such as asbestosis or other environmental harms, the time between payment of premium and an insurer’s obligation to pay on a claim may span decades. Moreover, individual policyholders or smaller businesses are often at a severe disadvantage in resolving disputes with large, sophisticated, and experienced insurers and generally have difficulty banding together to attain their common interests. Insurers thus must be forced by governments to be particularly prudent with their investments and to be responsible in the way they handle claims. Doctrines such as “contra proferentem,” “reasonable expectations,” “good faith,” and “intelligibility” often play significant roles in this latter effort, though the greater ability to provide information in the modern age may result in a larger role for regulation via ratings and reputation.

**INTERMEDIARIES**

Critical to the operation of the insurance industry are various intermediaries who bridge information gaps between consumer and insurer. Agents, who may work for insurers or groups of insurers, attempt to fit existing insurance products to the needs of potential insurance consumers. Brokers, or independents as they are sometimes called, serve as expert shoppers, assisting businesses of varying sophistication in the purchase of complex and often coordinated packages of insurance products. These intermediaries often permit prospective insureds to access insurance products offered by insurers in other states or nations that would otherwise be unavailable. Often, the law imposes on these intermediaries duties of diligence in assessing the fit between the insured’s needs and the products offered, the solvency of a proposed insurer, and in accurately transmitting information related to the risk posed by the insured.

**REGULATION**

Insurance tends to be a highly regulated industry. This is so in part because insurers have tremendous powers over the lives and fortunes of the individuals and businesses they insure (or refuse to insure) and in part because of their close resemblance to other large financial service industry players such as banks, whose ability to fulfill promises in times of need serves a vital social purpose. Because of the ability of insureds to cancel their insurance in most circumstances without severe financial penalty or to decline to renew their policies at relatively frequent intervals, insurance companies, like banks and other financial institutions, can lose capital rapidly. This fact means that even hints of trouble can precipitate a financial collapse with attendant financial and social ripples. Traditional insurance regulation attempts to reduce this risk through various forms of auditing, investment controls, government-sponsored backstop insurance and mechanisms to facilitate quiet recapitalization or merger of troubled insurers. In common law nations such as the United States and Commonwealth nations, courts have also been extremely important and influential in regulating insurers through the development of precedents regarding contract formation and interpretation.

In the United States, insurance regulation is conducted largely at the state level as a result of the 1868 decision of *Paul v. Virginia* and the substantial reconfirmation of that decision through the 1946 McCarran-Ferguson Act. There has, however, been an increasing role for the federal government, particularly in health insurance and, to a perhaps growing extent, in providing a backstop for insurance against terrorism. The McCarran-Ferguson Act generally displaces federal law regulating insurance, at least when a state is vigorously regulating the same subject, and specifically displaces most federal competition (antitrust) laws. The weakened role of competition law is said to foster healthy exchanges of information amongst insurers regarding risk and, on occasion, to regularize pricing in ways different than which would be achieved through competition.

In Europe, insurance is likewise subject to dual control, at the traditional national level and, increasingly since 1973, through directives from the European Community. Integration of these often disparate bodies of law and the various cultures and norms of these markets has been a significant challenge of the recent decades.
FUTURE PROSPECTS
The insurance industry faces new challenges in the years ahead. The industry will need to penetrate developing economic markets and adapt to local risks, regulation, and customs. As technology increases the ability to predict the future, risk pools may become more heterogeneous than they are presently perceived. Thus, unless long range contracting can be accomplished prior to the time prediction proves possible, or unless governments intervene with compulsory pooling mechanisms, insurance may become more difficult and more expensive for some groups to attain. Insurers will likely be called on to take heightened responsibility for the discrimination they foster through various rating practices that depend sometimes on accurate if unflattering information and sometimes on informational proxies that may neither be fair nor particularly accurate. Privacy issues likewise concern the insurance industry. As large aggregators of data, insurers will come under increasing pressure to develop codes of conduct relating to the assimilation and dissemination of information. Cultural or religious barriers to insurance are likely to come under pressure as various segments of the globe develop more mature forms of capitalism; and, indeed, the growth of “takaful,” mutual insurance that complies with Islamic limitations on purchase of commercial insurance, are symptoms of both this adaptation and expansion of the insurance industry. Finally, the industry will likely wish to develop mechanisms for handling new risks. Global climate change potentially poses significant risk to the insurance industry, which may grow in its advocacy for measures designed to reduce the impact of adverse weather conditions.

INTEGRATED PUBLIC USE MICRODATA SERIES
Integrated Public Use Microdata Series (IPUMS) refers to three distinct collections of individual-level data. IPUMS-USA is a coherent individual-level national database describing the characteristics of 100 million Americans in fifteen decennial census years spanning the period from 1850 through 2000. IPUMS-International includes data from 47 censuses of 13 countries, and new data are being added regularly. IPUMS-CPS provides annual data from the March demographic supplement of the Current Population Survey for the period from 1962 to 2006.

IPUMS contains information about both individuals and households in a hierarchical structure, so researchers can construct new variables based on information from multiple household members. Because it is microdata as opposed to summary aggregate data, IPUMS allows researchers to create tabulations tailored to particular research questions and to carry out individual-level multivariate analyses. Among key research areas that can be studied using the IPUMS are economic development, poverty and inequality, industrial and occupational structure, household and family composition, the household economy, female labor force participation, employment patterns, population growth, urbanization, internal migration, immigration, nuptiality, fertility, and education.

The database includes comprehensive hypertext documentation—the equivalent of over 10,000 pages of text—including detailed analyses of the comparability of every variable across every census year. Both the database and the documentation are distributed through an on-line data access system at http://ipums.org, which provides powerful extraction and search capabilities to allow easy access to both metadata and microdata. The National Science Foundation and the National Institutes of Health fund the project, so all data and documentation are available to researchers without cost.

IPUMS-USA is the oldest and best known of the three data series. It combines nationally representative probability samples produced by the Census Bureau for the period since 1940 with new high-precision historical samples produced at the University of Minnesota and elsewhere. By putting all the samples in a common format, imposing con-
sistent variable coding, and carefully documenting changes in variables over time, IPUMS is designed to facilitate the use of the census samples as a time series.

The sizes of IPUMS-USA samples are shown in Table 1. The only census year missing from the series is 1890, which was destroyed by fire. From 1970 onward, available samples include at least six percent of the population, and census years prior to 1970 cover approximately one percent of the population. Because the population grew rapidly in the nineteenth and twentieth centuries, the older 1 percent samples are considerably smaller than recent ones.

The large samples available for recent census years have proven valuable for study of small population subgroups, ranging from same-sex couples to the grandchildren of immigrants. In many instances, the large samples also permit the use of innovative methods; to take just one example, these files have allowed demographers to carry out multilevel contextual analyses by making it feasible to assess the characteristics of small geographic areas. Accordingly, projects are underway to create larger samples for the earlier census years. As shown in Table 1, higher-density samples are in preparation for the 1880, 1900, 1930, and 1960 census years.

IPUMS-USA is designed to encourage analyses that incorporate multiple census years for the study of change over time. The census has always contained certain core questions that are generally comparable over the entire time span of the database. Other questions have come and gone. Table 1 describes many of the subject areas covered by the census since 1850 (many of these topics correspond to multiple variables in the database). In general, the IPUMS samples include all the census questions available in each year, but for the period from 1940 onward, some detail is suppressed in order to preserve respondent confidentiality. In particular, geographic detail is far superior in the pre-1940 samples. In fact, the samples for the period prior to 1940 include the names and addresses of the respondents. On the other hand, topics such as income, educational attainment, and migration have only been covered by the census for the last six decades of the twentieth century. All IPUMS samples also include a common set of constructed variables to allow easy data manipula-
tion. Most important among these is a set of family inter-
relationship variables that have proven broadly useful in
the construction of consistent family composition and
own-child fertility measures.

In 2010 the scope of the U.S. census will be sharply
reduced. The Census Bureau plans to eliminate the
detailed long-form census questionnaire, and the census
will include only a few basic inquiries such as age, sex,
race, and relationship of each person to the householder.
Information about such topics as income, education,
housing, migration, or disability will instead be provided
by the American Community Survey (ACS). With virtu-
ally the same questions as the Census 2000 long form
questionnaire, the ACS provides data on three million
households each year. The ACS has released an annual
public use microdata file since 2000, and IPUMS has
incorporated these samples. For most purposes, ACS sam-
plings are closely comparable to those from censuses, so the
shift from census to surveys introduces only minor dis-
continuities to the data series.

Researchers who require annual data for the preceding four decades can turn to IPUMS-CPS, which provides a coherent version of the widely used U.S. population survey produced by the Bureau of Labor Statistics. The CPS includes virtually all the subject areas covered by the decennial census and the ACS, but provides much greater detail in certain areas, such as health insurance coverage.

The IPUMS-International project is extending the IPUMS paradigm to approximately fifty countries around the world. Large quantities of machine-readable microdata survive from census enumerations since the 1950s, but few of them are available to researchers and most are at risk of becoming unreadable. The first goals of the IPUMS-International project are to preserve machine-readable census microdata files wherever possible and to obtain permission to disseminate anonymized samples of the data to researchers. Then—just like the original IPUMS project—researchers convert the data into consistent format, supply comprehensive documentation, and make microdata and documentation available through a Web-based data dissemination system. Table 2 summarizes current and planned IPUMS-International data releases. The project began releasing data in 2003, and with information on 143 million persons, by June 2006 it already exceeded the scale of IPUMS-USA. The project has concluded agreements to preserve and disseminate data from some 200 censuses in 71 countries; negotiations with most of the other major countries of the world are underway. Information on the IPUMS-International release schedule is available at http://ipums.org.

**Integration**

Integration is the process by which individuals and groups come to interact freely and equally in society without regard to distinctions of skin color. In a completely racially integrated society, no systemic or institutional discrimination exists against the members of any racial group. Even if economic and cultural differences exist, these do not decrease access to employment, housing, politics, health, public services, and recreation for any racial group. Integration has both formal and substantive dimensions. Formal integration is based on principles, laws, and symbols that represent equality and nondiscrimination. Substantive integration involves the implementation (or actualization) of integration laws and is reflected in the significant and sustained incorporation of minority groups into the economic, political, and social institutions of the larger society.

By contrast, segregation describes a situation in which members of different racial groups rarely come into contact with one another or interact as social equals. Under segregation, separation along racial lines applies to nearly all aspects of life and those contacts between racial groups that do occur are socially controlled. Social distance is reflected in a “color line” that clearly demarcates dominant and subordinate groups. Segregation may vary from

de jure forms, which are overt, formal, and written into law, to de facto forms that are covert coded, and informal and exist independently of the law. In the United States, “Jim Crow” de jure segregation was dominant from the end of Reconstruction up until the early 1960s. In the North and West, however, de facto segregation based on custom and institutional discrimination was more prevalent.

Desegregation is the legal remedy used to bring about reforms in previously segregated institutions (Clark 1953, p. 2). While desegregation is often associated with “racial balance” and “racial mixing,” and is necessary for the achievement of integration, it alone is not sufficient to bring about racial integration. First, while desegregation meets the expectations of formal integration in that it follows the “letter of the law,” it does not meet those requirements of substantive integration that come closer to the “spirit of the law.” Formal integration places the burden of integrating on the disadvantaged group and is commonly accomplished through “token” efforts. Secondly, desegregation does not necessitate that people in the reformed institutions interact freely and equally and without discrimination. Resegregation can occur with desegregation. For example, efforts to desegregate schools may result in “white flight” or the establishment of different tracks in schools, with disadvantaged racial groups disproportionately assigned to lower tracks. Third, the implementation of desegregation tends to be uneven and is influenced by the history, culture, and politics of different regions and communities and the salience of local color lines.

INTEGRATION POLICY
RATIONALES AND IMPLEMENTATION

Racial segregation existed as both the “spirit” and “letter” of the law in the United States from the end of Reconstruction through the early post–World War II years. In 1896 the landmark Supreme Court case Plessy v. Ferguson declared racial segregation constitutional so long as public facilities were “separate but equal.” The development of a system of “Jim Crow” segregation, built on dominant American beliefs in white supremacy, was socially reproduced in institutions, organizations, and daily folkways and mores. Discrimination restricted most black Americans that remained in the South to farm, domestic, and unskilled labor, and disproportionately subjected them to involuntary servitude in the form of convict labor. Indentured jobs and union membership were mostly closed to blacks, and when blacks were hired they were often used as strikebreakers. Blacks also suffered economic discrimination when it came to securing land, credit, and public relief and social welfare. The disenfranchisement of most blacks from voting and jury selection occurred as a consequence of violence, lynching, intimidation, “white-only” primaries, and poll taxes. Segregation and discrimination also extended to public schools, libraries, churches, recreational facilities, transportation, and other public accommodations.

Rationales for integrationist policy eventually emerged in response to sociopolitical changes brought about by World War II and the cold war, and as a result of the growing struggle for racial equality. As the United States entered World War II and the moral and ideological imperatives of fighting against German fascism and Nazi racial doctrines became increasingly evident, American leaders turned to inclusive egalitarian values to justify the war. Black leaders, black newspapers, and civil rights organizations called for a “Double V” Campaign—form victory against both fascism abroad and racism at home. The large-scale military and economic mobilization of the United States during World War II and the early years of the cold war involved a significant number of black Americans, both in the military and in civilian society. Black Americans struggled against the segregation and discrimination that continued during wartime, as evidenced by A. Phillip Randolph’s March on Washington Movement (1941), which sought to end discrimination in defense industries, and by a campaign that threatened to mount civil disobedience protests against the segregation of the armed forces (1948). President Franklin D. Roosevelt’s signing of Executive Order 8802 (1941), which prohibited discrimination in industries receiving federal defense contracts, and President Harry Truman’s signing of Executive Order 9981 (1948), which integrated the armed forces, represented victories for these protest movements and provided precedents for substantive economic integration (Bennett 2003).

In the postwar period, the cold war between the United States and the Soviet Union and the international struggle to win the allegiance of newly independent non-white nations in Asia, Africa, and the Americas led to the articulation of enlarged moral and ideological imperatives favorable to racial equality. The convergence between these imperatives and the continuing struggles of black Americans and civil rights organizations against segregation and discrimination resulted in Supreme Court decisions and federal policies fostering integration (Klinkner 1999; Klarman 2004). Justifications for integration and desegregation policies also derived from practical considerations. By the cold war years, the cost of maintaining “separate but equal” schools and other facilities in the South had mounted substantially and was becoming increasingly impractical. “Equalization” strategies that were successfully used by the National Association for the Advancement of Colored People (NAACP) during the 1930s and 1940s forced many Southern districts that
wanted to maintain legal segregation to duplicate services and overspend on resources (McNeil 1983).

Those seeking to develop rationales for the implementation of integrationist policies were forced to consider two competing models of governance. A strong and centralized federal government with the ability to enact and forcefully implement civil rights laws was viewed as necessary by a coalition of liberal politicians and civil rights organizations who believed that only such a force could undo the historic and continuing effects of segregation and discrimination. It was recognized that reforms in segregation laws would open up the opportunity structure and improve the social and economic status of black Americans (Myrdal 1944; Clark 1953). Another, older conception of how racial justice might be achieved argued for reliance on local governments (i.e., “states rights”), and emphasized that states and local areas, rather than the federal government, should determine the appropriateness of laws concerning the functioning of institutions, including the color line. This conservative and segregationist coalition argued that only when the local folkways and mores had accepted the imperatives of racial equality should integration and desegregation occur.

The landmark Supreme Court decision Brown v. Board of Education (1954) illustrates the attempt to balance these competing conceptions of governance and, in effect, to reconcile integration and segregation. The Supreme Court’s invalidation of the “separate but equal” doctrine with respect to school segregation provided arguments that formally initiated school desegregation. With respect to implementation, however, the Supreme Court ordered no immediate remedy and deferred reargument until the following year (1955). The Supreme Court endorsed a “gradual transition” to desegregation (“with all deliberate speed”) that took local conditions into account and was sensitive to the “flexibility” of traditional principles of equitableness. The justices reasoned that immediate desegregation was unenforceable, impractical, and would lead to violence and school closures. President Eisenhower and the Justice Department supported a decentralized approach that would allow district court judges to return to the case and reargue it with limited guidance. By contrast, civil rights organizations such as the NAACP had urged complete and immediate desegregation (Klarman 2004).

Justice for integrationist policies also derived from the convergence between cold war domestic politics of the “Great Society” and the heightened mobilization of the civil rights movement during the early 1960s. The sustained mobilization of local organizing committees and movement organizations such as the NAACP, the Southern Christian Leadership Council, the Congress of Racial Equality, and the Student Nonviolent Coordinating Committee, along with the organized and sometimes violent resistance of local white institutional actors and communities, brought to America’s consciousness the contradiction between democratic ideals and continued segregation and discrimination. The enactment and implementation of integrationist policies signified that the goals of the civil rights movement were legitimate and had been met—and that it was thus no longer necessary to mobilize demonstrations and protests. Minimalist conceptions of integration emphasized the principle of each individual being judged only by the “content of their character” and not by racial, ethnic, or religious distinctions.

The integration policies enacted during the 1960s comprised the most sweeping civil rights legislation in American history. The Civil Rights Act of 1964 was designed to target and prohibit all aspects of discrimination: voter discrimination (Titles I and VIII), public accommodation discrimination (Title II), public facilities segregation (Title III), segregation of educational facilities (Title IV), and employment discrimination (Title VII). It also mandated Civil Rights Commission investigations (Title IV) and established various federally assisted programs (Title VI). Resistance in several Southern states to ending voter discrimination was met head on by the mobilization of civil rights organizations, which resulted in the passage of the Voting Rights Act of 1965. This allowed federal registrars to take over the voter registration process in areas where past discrimination existed and oversee the polls on elections. The passage of the Civil Rights Act of 1968, which prohibited discrimination in housing, followed the assassination of Martin Luther King Jr.

Implementation of nondiscrimination policies depended on the voluntary actions of private-sector corporations, businesses, and firms, on public-sector bureaucracies and agencies, and on federal enforcement agencies such as the Equal Employment Opportunity Commission (EEOC) and the Office of Federal Contract Compliance Program (OFCCP). The policy of prohibiting racial discrimination in the employment practices of businesses that hold contracts with the government was formally strengthened with President John Kennedy’s issuing of Executive Order 1375, which established an obligation on the part of federal contractors not only to refrain from discrimination but also to undertake “affirmative action” to ensure that equal employment principles are followed. The implementation of affirmative action as government policy took root under President Richard Nixon’s administration as the “Philadelphia Plan.” The government’s motivation for pursuing the Philadelphia Plan was largely political, as the policy was designed to drive a wedge between the civil rights community and organized labor (Klinkner 1999, p. 294). As affirmative action evolved it came to encompass various programs and measures to improve the educational, employment, and busi-
ness opportunities of racial minorities, women, and other socially disadvantaged groups.

Integration affirmed the principles of democracy and equality and sought the progressive inclusion of black Americans into the institutions and organizations of American society. As with nondiscrimination policies, the implementation of integration policies depended in practice on the voluntary actions of private-sector corporations and businesses, on public-sector bureaucracies, and on federal enforcement agencies. At the same time, federal court decisions mandating school desegregation were constrained by cautious gradualism, the persistence of localism and "states rights" governance, and high levels of racial segregation in the largest cities, where blacks were increasingly living. Federal integration policies had their most immediate impact in the South, where there was a history of de jure segregation.

While the effects of integration were immediately evident in the desegregation of public accommodations and the extension of voting rights, these advances did not translate into economic integration (or economic rights). After 1965 Martin Luther King increasingly emphasized the goal of achieving economic equality, which, he argued, would derive from: (1) the refocusing of macroeconomic policy from military-industrial spending and the Vietnam War to domestic economic spending and the poor; (2) improving black economic competitiveness through education and training; and (3) blacks leveraging their buying power by boycotting specific goods and services (King 1968). King's opposition to the Vietnam War and his support for the Memphis garbage-workers strike and the Poor People's Campaign were intertwined with his advocacy of economic rights. Since the late 1960s, civil rights organizations have followed King's lead by embracing affirmative action, "set-asides," "moral covenant" policies, and minority franchises (Walker 1998).

That integration was a dream deferred was made evident by the Kerner Commission's report, which warned that America was increasingly becoming two societies: one black, and living in the central cities; the other white, and living in the suburbs (National Advisory Commission on Civil Disorders, 1968). Integration's inability to address the social and economic conditions of the black masses and continuing conflicts between blacks and whites over education, jobs, housing, and the police led to the emergence of separatist and nationalist movements during the 1960s. Malcolm X, a national spokesman for the Nation of Islam, argued that black nationalism and separatism, rather than integration, were necessary for black empowerment and social improvement. Within segregated communities and ghettos, blacks were challenged to develop a sense of history, social consciousness, and solidarity and to support black institutions and organizations that would enable freedom and self-determination (Breitman 1990). The emergence of the black power movement signaled the fact that instead of embracing integration, blacks were increasingly "closing ranks" and seeking to control political and other institutions in black communities. At the same time that it criticized integration and black liberal coalitions, the black power movement introduced the concept of institutional racism to identify the complex intersection between institutional actions, cultural beliefs, and policies that contribute to the subordination of blacks (Carmichael and Hamilton 1967).

While federal policies of integration and desegregation began to reshape race relations in the South, in the North and West there was much less recognition on the part of white Americans that racism, discrimination, and segregation existed.

THE PERSISTENCE OF RACIAL SEGREGATION AND RESEGREGATION

The introduction of federal programs intended to foster integration was largely initiated during the cold war years of the 1960s. During the post–civil rights years of the 1970s, 1980s, and 1990s, the declining significance of cold war ideological and moral imperatives and of New Deal coalitions in national Democratic Party politics was accompanied by the rise of increasingly conservative political and social movements urging resistance to integration and racial equality. While the universal principles of integration were widely embraced, programs to implement integration and desegregation were frequently resisted (Schuman, Steeh, Bobo, and Krysan 1997).

The retreat from racial equality and the dismantling of programs intended to foster desegregation and integration have taken several forms. First, institutions such as the Supreme Court have retreated from strong interpretations of school desegregation, minority "set-asides," and affirmative action. At the same time, federal agencies such as the EEOC and the Fair Employment Practices Committee have been weakened by diminished funding. Second, in policy discussions and popular discourse affirmative action and integration programs are being redefined as "reverse discrimination." Although affirmative action applies to protected classes defined not only by race, but also by gender, age, and disability, and although enforcement of gender-based affirmative action largely surpass race-based enforcement, the discourse of "reverse discrimination" largely relates to the politics of racial resentment. Third, white Americans' perceptions and
beliefs concerning race-based economic inequality are more likely to emphasize individualistic explanations than structural or systemic explanations (Kluegel and Smith 1986; Kluegel 1990).

Despite important civil rights reforms such as Brown v. Board of Education (1954), the Civil Rights Act of 1964, the Voting Rights Act of 1965, the Fair Housing Act of 1968, and affirmative action, racial segregation continues to socially structure housing, education, the workforce, and other social institutions and organizations. Racial segregation remains a widespread social relationship, practice, and symbol of racial and ethnic inequality in American society. Continued patterns of segregation experienced by racial minority groups symbolize and actualize the lower social status of these groups in the social hierarchy and their limited access to opportunities and resources connected to the American Dream.

During the post–civil rights years, high levels of black segregation have continued despite small but steady decreases in segregation in those metropolitan areas with the largest black populations. Sociologists use a “segregation index” to measure the degree of segregation, ranging from 0 for full integration to 100 for complete segregation. In 2000 the average black-white segregation index in U.S. metropolitan areas was 65, and in the Northeast and Midwest it was 74 (Iceland, Weinberg, and Steinmetz 2002). Based on a multidimensional construct of segregation with five dimensions of spatial variability—evenness, isolation, clustering, and concentration—and scores of at least 60 on four of the five dimensions, twenty metropolitan areas were identified as “hypersegregated.” Together, these contained roughly eleven million black Americans (in 1990) and constituted 36 percent of the entire U.S. black population (Massey and Denton 1993).

Hispanic segregation in metropolitan areas has been more moderate, with average scores ranging from 46 to 55 (between 1970 and 1990) (Denton and Massey 1988), and Asian segregation has been relatively lower than both black and Hispanic levels (averaging from 36 to 44 between 1970 and 1990) (Massey 2001, pp. 407–409). One of the most salient features of segregation is the concentration of blacks in central cities and whites in suburbs.

Racial segregation tends to be socially reproduced across institutional contexts. Individuals in racial groups who are segregated in one institutional area—whether in housing, education, employment, criminal justice, or informal social interactions—are also likely to have mostly segregated experiences in other institutional environments.

The persistence of internal segregation in schools derives from institutional relationships and public policies. High levels of residential segregation are associated with commensurate levels of racial segregation in schools. Although school segregation decreased between 1968 and 1980 as a result of judicial enforcement, during the 1980s and 1990s governmental inaction and deregulation of mechanisms to desegregate schools led to increasing resegregation. In many school districts where court-mandated desegregation has ended, there has been a major increase in segregation (Orfield and Lee 2004). Levels of school segregation have been higher in the Northeast and Midwest than in the South and West (Orfield 2001). The abandonment of desegregation as public policy has mirrored the rise in national politics of the assumption that segregation and racial inequality are historic problems that have already been addressed. Contemporary movements to expand educational choice, through publicly funded vouchers that enable students to attend private schools, are occurring in a context in which the civil rights afforded by the Brown decision are being detailed.

Racial minorities who attend racially segregated urban schools are less likely to take college preparatory courses and attend college than those in more integrated and suburban schools. Teacher assignment practices reinforce inequality, because the least proficient teachers tend to be assigned to the least desirable schools, which are often in minority neighborhoods. Yet even in more integrated schools, minorities experience disadvantage due to lower expectations on the part of teachers and placement in lower tracks.

During the post–civil rights years, continued improvements were made in high school graduation rates across racial groups, which was reflected in a narrowing of the racial gap. Although actual and percentage levels of college graduation increased for all groups during the 1990s, there has been a growing racial gap in college attendance rates between whites and blacks and between non-Hispanic whites and Hispanics (Blank 2001, pp. 25–26). Recent efforts in higher education to increase academic standards and eliminate affirmative action have come at the expense of continued movement toward racial equality and educational opportunity.

Continuing racial segregation and discrimination has affected wealth accumulation, earned incomes, and employment chances across racial groups. Racial differences in wealth, which reflect intergenerational wealth and current asset ownership, are more extreme than income differences. Wealth differences are reflected in differences in levels of home ownership, which are not merely the result of income differences but rather a product of the historical legacy of residential segregation, Federal Housing Authority and Veterans Administration policies, and redlining. Blacks are rejected for home loans 60 percent more often than whites with the same income level, black families pay more in mortgage interest than
Segregation in labor markets, which are associated with different formal and informal social networks, is reflected in higher rates of unemployment and joblessness among racial minorities. Unemployment rates for both blacks and Hispanics have remained roughly twice the white unemployment rate. Among the factors contributing to high joblessness rates are selective recruitment and statistical discrimination, employer practices that reduce access to jobs for inner city applicants. These may involve limiting recruitment to selective neighborhoods, avoiding the placement of ads in central city newspapers, passing over applicants from black public schools, and subjective tests of job productivity (Wilson 1996, pp. 133–136).

Segregation and deprivation among blacks have been accompanied by criminal justice policies with impacts that are highly differentiated by race. “Racial profiling” by law enforcement associates particular racial and ethnic characteristics with dangers, risks, and threats. The federal Anti-Drug Abuse Act of 1988 prescribes the same mandatory-minimum sentence for 50 grams of crack cocaine (a form of the drug more likely to be used by low-income blacks) as it does for 5,000 grams of powdered cocaine (a form more likely to be used by high-income whites) (Blumenstein 2001, p. 26). An individual caught possessing only 1 to 5 grams of crack cocaine is subject to a mandatory minimum sentence of five years in prison. Crack cocaine is the only drug for which there exists a mandatory minimum sentence for the first offense (Kennedy 2001, p. 15). More than 30 percent of black high school dropouts will go to prison at some time in their lives, compared to 10 percent of white male high school dropouts (Patillo, Weiman, and Western 2004). Among black males in their twenties, 30 percent were under the control of the criminal justice system—prison, jail, probation, or parole (Mauer 1990).

When U.S. integration policies were first adopted, race-based discrimination was officially recognized and black-white relationships were the primary focus of formal and substantive integration. Through the 1960s, the federal government and its civil rights agencies were expected to end legal segregation and discrimination. By the post–civil rights years, the goals of integration had expanded into a policy of diversity, which policymakers struggled to implement. While civil rights organizations have emphasized that integration programs should be sustainable and relatively enduring considering the long history of slavery and segregation, there is a growing tendency among politicians to view integration as a set of transitional programs that have “run their course” and are no longer necessary. New patterns of integration emphasize formal integration and are based on the principle of “colorblindness,” which argues that people should be treated as individuals and not as members of groups. By asserting that race does not matter, colorblindness as a principle and social policy denies the reality of continued discrimination. At the beginning of the twenty-first century, racial segregation and institutional discrimination persist in the United States despite the emergence of a colorblind society.

INTEGRATION IN CROSS-NATIONAL CONTEXTS

The philosophical bases for the adoption and implementation of integration policies in the United States may have been informed by similar attempts to promote racial and ethnic integration in other societies such as India, Brazil, Britain, and France. Integration policies in these countries have varied with respect to their emphasis on either formal or substantive integration, their articulation of race and racial discrimination (as distinct from ethnic and class discrimination), the role of the government and government agencies, and the demographic characteristics of racially and ethnically subordinate groups. Differences also exist regarding the question of whether such programs should be viewed as transitional or long-term.

India’s integration policy, the “reservation system,” grew out of the larger Indian struggles for home rule and independence, which had as one of their goals the elimination of the caste system. The Indian caste system, which existed for more than 2,500 years (up until 1947), was a status hierarchy and occupational stratification system with religious, color-based, and regional dimensions. Under the country’s constitution, the “reservation system” sets aside a proportion of all government jobs, seats in educational institutions with government funding, and electoral constituencies for persons from “scheduled castes,” “scheduled tribes,” and “other backward classes” (Deshpande 2005, p. 10). Because Indian integration policies are based on the constitution, they cannot be legally challenged. National minority status, rather than racial status, is the basis of assignment to one of the protected classes. Unlike the United States, integration is based completely on voluntary efforts. Greatest resistance to the integration of the “untouchables” has come from the highest castes, which are highly represented in the decision-making positions of government. Critics of India’s integration have emphasized that the poorest and outcast “scheduled castes” and “schedule tribes” are greatly outnumbered by the “other backward classes” and that the “quota system” has selected from the more privileged members of these underclasses and not the poorest. At the same time, many of the slots made available by the quota system go unfilled due to low levels of education, training, and preparation among low-caste groups (Sowell 2004).
Brazil's integration policies have been constrained by a national ideology that views the country as a "racial democracy," a self-perception supported by the absence of legalized racial segregation, substantial miscegenation and interracialism, and a constitutional provision of equality before the law. Until recently, race as an official category did not exist and public discussions of the "racial question" were officially prohibited. The ideology of "racial democracy," which maintains that race does not matter, is intricately combined with an informal system of discrimination and a social hierarchy of color (or "pigmentocracy"), in which lighter skin is associated with greater prestige and economic status and darker skin is associated with lower prestige and poverty. Under the dominant cultural belief system, African ancestry or blackness was defined by the European elites as anti-Brazilian. Relatedly, among blacks the notion of a color-blind "racial democracy" has undermined the legitimacy of organized struggle and the development of collective consciousness, self-help, and uplift. During World War II and the postwar years, any possibilities of integration in Brazil were further thwarted by two major periods of authoritarian rule (1937–1945 and 1964–1985) (Nascimento and Nascimento 2001).

More recently, Afro-Brazilian activists have struggled to have the “racial question” recognized as a national issue and have demanded the articulation of specific public policies addressing racism. At the same time, the number of Afro-Brazilians elected to political office and in other positions of power has increased, though it is still very far from proportionate. Also, racism is increasingly coming to be viewed as a question of human rights. In the late 1990s, President Fernando Henrique Cardoso publicly denounced racism and began to introduce affirmative action programs for Brazilians of African descent. The government of President Luiz Inácio Lula da Silva (2002–present) created the Special Ministry to Promote Racial Equality and state universities in Rio de Janeiro, Bahia, and Minas Gerais began the policy of reserving vacancies for blacks and public school students. The Brazilian Congress has also introduced bills that mandate quotas for all public universities, government services, and television shows. The implementation of affirmative action policies in the universities has derived from the convergence of Afro-Brazilian struggles and new governmental policies.

In Britain and France, official recognition of race, ethnicity, and discrimination was virtually absent until after World War II. In both countries, the large-scale influx of immigrants from former colonies in the Southern Hemisphere led to a perceived need for integration policies.

British integration policies grew out of legislation that was initially designed to restrict immigration and depoliticize race. In response to the growth of West Indian and East Indian immigrant populations, in 1964 the Labor-dominated British government enacted legislation that both restricted immigration and encouraged integration (Bleich 2003, pp. 65–66). Four years later, a progressive coalition brought about the enactment of the more comprehensive 1968 Race Relations Act, which made discrimination on racial grounds unlawful in housing, employment, training, education, and the provision of goods, facilities, and services. This legislation established an administrative agency for race-related issues, structured access into British institutions, and widened protections against racism. Paralleling developments in the United States, the 1968 Act reframed issues of integration as issues of access. The British Parliament expanded the definition of discrimination from direct intentional discrimination to indirect discrimination, whether intentional or not, and laid out a soft form of affirmative action known as positive action (Bleich 2003, pp. 101–102). The Race Relations Amendment (2000) extended the coverage of the 1976 Act to all public institutions, with only a few limited exceptions. Since the 1976 Race Relations Act, movement toward increased access has been constrained by institutional changes—such as decentralization, which saw political power shift to the judiciary, local jurisdictions, and the bureaucracy—and, beginning in the 1980s, by a succession of conservative-led British governments that were not receptive to “race-conscious” policies addressing indirect discrimination.

France’s antidiscrimination policies derived from French memories of Nazism, anti-Semitic newspapers, and speeches by far-right demagogues. Protections against unequal access to employment and services were negligible. Focused largely on formal integration and “expressive racism,” French integration legislation introduced in 1972 criminalized racial defamation and the provocation of racial hatred against groups or individuals; outlawed discrimination in hiring, firing, and the provision of goods and services; and enabled the government to disband groups that seek to promote racism. Protections against unequal access to employment and services remain negligible (Bleich 2003, pp. 139–141).

French legislation conceived of discrimination as based on religion or ethnic or national origin—but not on race. France has a “colorblind” code that omits the word race. The government collects no census data relating to race and ethnicity, and in 1978 it banned race-based statistics. There is no public- or private-sector use of racial or ethnic data to estimate the status of minorities (Bleich 2003, p. 141). Although the immigration of North and West Africans has continued, and immigrants in France...
experience substantial economic inequality and segregation, structural discrimination and unequal access are not recognized in France's integration policy.

INTELLECTUALISM, ANTI-

It is difficult to define anti-intellectualism with precision. In the simplest sense, the term expresses enmity against the life and works of the mind and adherence to allegedly unmediated practicality. Still, it is hasty to assume that this resentment of the intellect pertains to actions or practices devoid of intelligence. The name silences a basic contradiction. Anti-intellectualism refers to a certain tendency or mentality, therefore a specific state of mind, that paradoxically refuses to recognize the capacity and value of the mind.

It would be misguided to take anti-intellectualism at its word and determine that it consists of unexamined sentiment, pious faith, common sense, or unmitigated pragmatism. Anti-intellectual discourses deployed against ideas and values thereby pronounced dangerous are themselves propelled by a whole complex of ideas. However—and here lies the contradiction—these ideas must remain strictly unacknowledged; their presence and exercise must be denied. In this respect, there is something ideological about anti-intellectualism, or perhaps it is more accurate to say that anti-intellectualism is likely to adhere to the primacy of an ideological, rather than critical, relation to the world. This can be said despite the claim that in certain instances of modern history, under the banner of populist egalitarianism, anti-intellectualism was deployed in order to break down various ideologies of privilege.

Given anti-intellectualism’s paradoxical conditions—whether we examine it as an idea, an attitude, or a historical phenomenon—it is most productive to trace its multiple and fluctuating reference frames rather than to insist, in anti-intellectual fashion perhaps, on its self-evident nature. As a departure point, we may take anti-intellectualism to consist of whatever discourse subverts conditions that enable intellectual life to flourish: an open horizon of interrogation, a plurality of sources of knowledge, the right to dissent, the freedom to challenge certainties and authorities, the capacity to pursue independent research and investigation. The means of subversion is to foster instead a climate of dogmatism and conformity, often driven by narrow and politically expedient aims, that enforces a closed system of thoughts and beliefs exercised throughout the social sphere, though often concentrated in the realms of religion, education, and mass culture. Anti-intellectualism triumphs when such conditions strangle not only the terms of intellectual life but also the very essence of democratic existence.

Anti-intellectualism in the United States should be considered “older than national identity itself,” as Richard Hofstadter succinctly put it in his *Anti-intellectualism in American Life* (1963), which remains the consummate treatment of the subject. Published a few months before the assassination of President John F. Kennedy, at a time of tremendous intellectual optimism in U.S. politics and obviously unwitting of its imminent collapse, Hofstadter’s book sought to theorize the conditions that produced McCarthyism—one of the gravest instances of American anti-intellectualism—by thinking backward, in broad historical terms, in order to elucidate a phenomenon with deep roots in American society.

Certainly, the anti-intellectualism that brought Dwight Eisenhower to power in 1952 against Adlai Stevenson (in whose name the term egghead achieved popular usage) could be seen as a replay, in another historical register, of the same attitude that brought Andrew Jackson to power against the privileged and bookish easterner John Quincy Adams. What became known as the Jacksonian Era (1824–1840) is traditionally considered to be a period of emancipatory democratization in U.S. history, and yet this is when the down-home posturing of David (“Davy”) Crockett in the corridors of the U.S. Congress, his vulgar and contemptuous response to the American Enlightenment tradition, elevated him to what by today’s standards would be a mass-cultural icon.

The anti-intellectualism exemplified by Crockett and many Jacksonians, which led to the “decline of the gentleman” in the American social imagination (Hofstadter 1963), does not automatically dispel the genuine argument that the Jacksonian Era signified real democratic expansion. Conversely, however, any argument henceforth about the processes of social democratization in the United States cannot avoid being tainted by suspicion of anti-intellectualism, a tradition that has repeatedly marked U.S. history by, if nothing else, driving the country into periods of self-imposed denial of the surrounding world, with disastrous social, political, and cultural consequences.

This early historical instance is a good example of how the study of anti-intellectualism might produce an equivocal assessment. For the Jacksonians, anti-intellectualism was an explicit platform against established class privilege, represented by the rich, powerful, and highly educated old New England families. In this respect, it served as means for upward mobility, as a weapon in a classic case of class warfare, whereby the intrinsic intellect or “know-how” of less educated folk—one might say, the entrepreneurial capacity (or autodidact practical intelligence) of the unprivileged bourgeoisie—was celebrated as the only genuinely American way of being. This is to say that the proponents of anti-intellectualism in the Jacksonian Era were not uneducated farmers or workers; they were educated middle-class men who sought (and got) a piece of the pie of privilege in the name of expanding the range of opportunity for the uneducated and the unprivileged (farmers or workers). Jackson's people were
great populist propagandists. In this sense, they managed to portray the Jackson-Adams presidential race as a context of the representative of vita activa versus the representative of vita contemplativa, considering the latter to be too weak for the task of the presidency. The outcome of this contest legitimized a social and political imagination that drew its authority precisely from defying the Union's Enlightenment foundations, revering them as mere constitutional legacy while disregarding them in real life.

Conversely, one may just as easily argue that the Enlightenment tradition is only one strain of American foundation, obviously linked to the revolutionary politics that brought to this society a national existence. The other strain, less directly political but nonetheless profoundly social, is the morality of Christian Protestantism, particularly the pietist and Puritan strains of the early colonists. This aspect animated a certain imaginary in which communities formed by subsequent waves of immigration, even when not necessarily Puritan or even Protestant in a general sense, found solace and identification. It is this imaginary of Christian moral authority and Puritan work ethic, and not the Enlightenment imaginary of the nation's intellectual founders, that mobilized Western expansion and immigrant assimilation. This imaginary is constitutively anti-intellectual because it is essentially moralist and, more specifically, religious in its moralism. As one strain of a bifurcated social-imaginary foundation, anti-intellectualism is thus fundamental in American society, even if it is not consistently dominant in the public sphere.

Certainly, the contemporary emergence into political power by the Christian Right, with its explicit religious and moral fundamentalism, is but one more manifestation in a long history of evangelical participation in the American anti-intellectual tradition. The incessant drive to displace Darwinian theories of evolution from the high-school science curriculum in favor of creationism is an obvious such instance, signaling a profound reversal of a matter considered resolved in the 1925 Scopes trial. But equally obvious are the attempts to strong-arm court appointments at all levels of the justice system, where the actual stakes ultimately reside in a battle for an open framework of discussion and argument over interpretation of the law according to predetermined ideological principles that regard the institution of law not as a human enterprise and endeavor but an indication of the word of God written in stone. The current alliance between Christian evangelists and neoconservative ideologies at the highest levels of U.S. government elucidates the deceptive anti-intellectualism of the latter. Although the so-called neocons are all highly educated men, many of them with academic careers, they nonetheless espouse a vision of American society where plurality of views, open interpretation, interrogation of received knowledge, and, of course, dissent—the cornerstone of democracy—are rendered null and void.

Not surprisingly, the avowed enemies of contemporary anti-intellectualism reside in education and in media, two domains of enormous influence in matters of formation, cultivation, and refinement of democratic consciousness. But this current development has its roots in the Right's reaction to the United States' post-Vietnam conditions, particularly the fact that the student movement and an independent press played the most crucial role in the demise of the Nixon administration. Since the 1980s, U.S. social services and civil liberties have confronted the most orchestrated onslaught of government-based anti-intellectualism to such an extent that, for example, the “dumbing-down of American universities” turned from a slogan to a reality that is now statistically confirmed. With public primary and secondary schooling driven to bankruptcy due to fiscal restructuring that relegated education the lowest priority, the whole function of university education (anchored to its definitional demands for higher learning) is thus incapacitated. Although one surely finds anti-intellectual strains within academic ranks, of greatest concern regarding society's future is the increasing anti-intellectualism of the student population. This is manifested on campuses in myriad ways, from objections to types of courses and course materials to demands for uncritical expressions of opinion in the classroom in the name of objectivity or so-called balanced accounts.

American youth, however, cannot be blamed for what is de facto the “dumbing-down” of an entire country, which is most visible in the extraordinary manipulation and spectacular vulgarity that characterize contemporary media. Although there was a time one could count on investigative reporting to expose social and political injustice, thus restoring the democratic capacity of ordinary citizens, in the early twenty-first century one sees journalists, embedded in the political status quo, who merely seek to outdo each other in showmanship, quick and empty sloganeering, and allegedly bottom-line pronouncements. It is this talent for catchy slogans and cheap bravado that marks the ideological reversal of certain once-upon-a-time scions of the intellectual Left, such as David Horowitz and Christopher Hitchens, who now grace the front lines of neoconservative platforms. However we might judge whether and to what extent their politics (one way or another) were ever genuine, what accounts for their new conservative prominence is their blatant anti-intellectualism. In addition to narcissistic posturing in the media, the need to push the reporting of events through the newsitem assembly line with the greatest possible speed, in the service of higher viewer ratings, feeds the anti-intellectualism that conceived of embedded journalism in the first place. It is certainly no surprise that American academics and intellectuals of great stature are nowhere to be seen in

65
the mass media. They are effectively censored, not merely because of their independent views but also because of their refusal to speak in advertising slogans, because their language has been rendered incompatible with the media's current production values.

It must be said, however, that responsibility for the charge that intellectuals are out of touch with the people because they speak a language that no one understands, a charge espoused so effectively by the agents of anti-intellectualism, rests on the shoulders of intellectuals themselves. Indeed, the best way to resist anti-intellectualism is by cultivating an intellectual life that: (1) does not let the attraction to concentrated and detailed knowledge become an endeavor of uncommunicative specialization; and (2) does not let the pleasure in concentrated and expert research get in the way of active participation in the public sphere of ideas and practices. In effect, anti-intellectualism will have no opposition from which to draw its menacing energy if the distinction between vita activa and vita contemplativa is rendered irrelevant.

INTELLECTUALS, ORGANIC

Rejecting the very idea of the disinterested scholar, Antonio Gramsci (1891–1937) in The Prison Notebooks (pp. 3–23) argues that all intellectual activity arises from specific socioeconomic circumstances. In fact, each sector of society yields its own variety of organizers, creators, mediators, and contemplators, whom Gramsci labels “organic intellectuals.” In so arguing, Gramsci recasts some of the key notions of modern political thought: hegemony, civil society, class difference, and the national-popular. More recently, Gramsci’s organic intellectual has served as a key concept within, or in opposition to, structuralist and poststructuralist theory, including postcolonial studies (Edward Said), subaltern studies (Renajit Guha), cultural studies (Stuart Hall, David Lloyd, Paul Thomas, Grant Farred), ethnic studies (George Lipsitz), post-Marxist thought (Jacques Rancière), and critical pedagogy (Henry Giroux, Michael Apple).

Gramsci introduces his notion, first, by insisting that education does not emerge from but actually creates the political foundations of the state; and second, by contesting existing views on traditional intellectuals. Typically seen as bearers of universal reason and general truths, such intellectuals in fact originate from the ecclesiastics qua the organic intellectuals of the aristocracy, and later take their place as subjects and agents of a particular historical block: the bourgeoisie. That the elite scholar is actually organic to a class, historical development, and social circumstance (points that Giroux and Apple emphasize) indicates as well that the division between the educated and uncultured, the cultured and uncultured, is not natural or necessary but contingent: a result of specific intellectual activity, whose true, if unspoken purpose, is to produce and reproduce these oppositions.

As to the working-class intellectual, Gramsci focuses upon the way in which the hegemonic state induces the consent of this group through the channels of an increasingly uniform civil society: the schools, the media, the Church, and so on. Gramsci’s well-known Prison Notebook assertion that “all men are intellectuals” lies here (p. 3). Because assent on the part of the oppressed or working class turns on a nonviolent, rational acceptance of official discourses and edicts, intellect and reason are conditions even of that subjugation. The point, though, proves double-edged: If intelligence is the requisite of the worker’s or peasant’s suppression, the capitalist state cannot not risk generating the alternative interventions that upset its order, even though its goal (homogeneity, consensus) depends, precisely, on the eradication of those alternatives. And when the state confronts another reason and the reason of the other it is forced to swallow them repeatedly: Devour an exterior, unfamiliar, deleterious intellectual legitimacy—as opposed to an irrational or wild outside, which the state can always cast as hazardous, and thus annihilate in the name of right—into its common sense, transforming itself into a dynamic process of assimilation, transmutation, and becoming.

None of this means that organic intellectuals sprout, like plants, from the material ground into which they are born. They are contingently, not essentially, bound to a class base. The organic is not the natural. In fact, in order to realize themselves, organic intellectuals must venture into alien arenas, including if not especially the realm (the
metropolis) of universal reason, represented by the state. Intellectual activity is a perpetual outing. For example, manual laborers such as metalworkers must familiarize themselves with state edicts, disconnected from their daily labor, if they are to initiate an effective legal appeal for improved lathes, that is, for better safety conditions. Likewise, the attorneys who handle the appeal must, through communication with workers, attain detailed practical and technological knowledge of the lathe, possibly altering their daily contacts, the texts that they study, the library where they conduct the research, and the vocabulary of their briefs to do so. Unplanned constellations, leading to unintended though not accidental (for they are products of work) interventions, surface as the various classes and/or types convene: Out of a congregation of lawyers and manual laborers concerned with worker well-being emerges a non-class-based women's collective seeking state-sponsored child care. Such cross-professional encounters, moreover, generate novel jargons and idiocles. These both permit the diverse sectors to communicate and represent potential foundations for future expertises and experts, for new tasks grounded organically in the invented vernaculars and emergent gatherings.

Traditional education, Gramsci argues, involves the repetition, delivery, accumulation, coordination, and control of existing as well as new ideas. It both manufactures and casts as inevitable, as a matter of common sense, a current “state of affairs” whose base is class difference. Indeed, as the officialdom is naturalized, it need not even be taught: The commonsensical, by definition, goes without saying, thereby without teaching. The aim of public state education, it would seem, is its own obsolescence, as well as the obsolescence of the alterity that education oftentimes generates. Conversely, organic intellectuals, charged by Gramsci with the boosting of education via its revolutionary overhaul, forge the idioms that link, coming between and disrupting this accretion of familiar signifiers, and of the status quo that they represent. Class difference resurfaces through these connections and articulations as class relations: relative, contingent, and precarious, like class itself. Because they are neither inside nor outside (but between) the established fields of meaning, these relational formulations materialize beyond sense and nonsense, effecting a demand for interpretation and intelligibility, that is, for thought. Who will meet the challenge, broach and articulate the uncommon sense—the organic intellectual who could deploy it for novel activity, for the renovation of the social field itself, or the traditional intellectual who will either appropriate or eradicate it in the name of greater hegemonic expansion? Because, by logic, either could, the class struggle is traversed through and through by these questions of education, knowledge, and creativity.

The responsibility of the organic intellectual, then, is less to insert newly legitimized knowledges into the aggregate of thought, hence to displace the extant field, than to disclose the fact that current conditions do not go without saying. The class injustices that sustain the state are not present by nature; therefore, they can be altered. Leftist politics remains conceivable. Organic intellectuals are not working-class heroes but, as Gramsci put it in the Prison Notebooks, forgers of the bond between the homo faber and homo sapiens (p. 4), making and saying, practice and theory. Effecting the suspension of the common sense, they cut through, gnaw away from within, relay and relate the provisional nature of the capitalist state, which cannot stand without clear class oppositions, the very oppositions that the organic intellectual’s labor calls into question.

Interestingly, recent scholarship that recurs to Gramsci’s notion often departs fruitfully from the Italian philosopher’s conceptualization—in part due to Gramsci’s class- and state-based foundation, and in part due to the new interest in cultural difference and identity. Often focusing on transnational, largely cultural uprisings (examples include the civil rights movements in North America and the Caribbean, and Pan-African unrest) these studies tend to employ as their models activists, poets, and scholars such as Frantz Fanon and C. R. L. James—figures who demonstrate the way in which the organic intellectual, when recast, can play and indeed have played major roles in actual, contemporary insurgencies.

INTELLECTUALS, PUBLIC

The term public intellectual has no meaning outside of an American context. Nowhere in the European tradition, for example, does one find references to this term because, strictly speaking, it is redundant. Intellectuals are distinguished from scholars or scientists because their role is necessarily public. They may indeed be scholars and scientists, academics and specialists in a particular discipline, and they may also be writers or artists, but they become intellectuals when the knowledge and learning they represent goes beyond the strict domain that gives them authority. Intellectuals achieve this status when their learned experience, their capacity for inquiry, interpretation, and speculation, is trained upon problems that concern the society to which they belong and, in the global epoch, problems that concern humanity and the planet as a whole.

That "public intellectuals" emerge into the English language as a specifically American idiom is indicative of a historical framework and tradition where anti-intellectualism carries a deeply imbedded and formidable legacy. Still, the term has a short history; it belongs to the latter half of the twentieth century. No one would think of identifying Thomas Jefferson (1743–1826), Benjamin Franklin (1706–1790), or Thomas Paine (1737–1809) as public intellectuals, though they were obviously intellectuals of great stature and public figures of enormous renown and influence. Though eighteenth-century scholars agree that Enlightenment ideas flourished politically because they coincided with (perhaps even had a hand in bringing about) the first vestiges of a veritable mass culture and the public sphere it demands, it is nonetheless a mark of the considerable alienation of intellectual life from politics in America that public intellectuals have become necessary as a specifically designated category since the Vietnam War. The term's redundancy raises questions in both directions: (1) What is the public (or even, is there a public?) that renders the role of intellectuals meaningful, and (2) of what must the role of the intellectual consist in order to merit (and achieve) a public?

The term intellectual itself is entirely modern, emerging during the great public debates in France over the Dreyfus affair (1894–1899). The elements of that specific historical conjuncture—the fact that citizens of learning engaged over a political issue (which, moreover, touched on fundamentals of national character)—cannot be maneuvered. It is not enough for intellectuals to apply themselves to the work of the intellect, or even to engage the world intellectually. It seems inevitable that intellectuals carry a political significance, that intellectual work is acknowledged as a domain of acts and practices that pertain to the political demands and conditions of the world they inhabit. It comes as no surprise then that the question of the role of the intellectual is one of the most debated issues in the Marxist tradition, with Antonio Gramsci's (1891–1937) famous theorization of intellectual positions having served as a departure point for subsequent theorizations even outside the Marxist canon. It is precisely because the role of the intellectual has assumed a political significance since the term was invented—in other words, that intellectuals achieve meaning only within the parameters of the polis—that the newer term, public intellectuals, inheres a redundancy.

Nonetheless, the current usage defines a particular object and deserves specific focus, as if the explicit insistence on the word public bears a need at the core for bringing attention to a lack. Only a society that develops a public sphere in which intellectuals are marginalized develops a need for the category of public intellectual. The marginalization of intellectuals in America is not ideologically driven, despite the grand tradition of anti-intellectualism. The causes are complex, but two factors must be specifically accentuated. First, there are real social-historical changes affecting the base of American politics since the 1950s, most important of which is the shift in the demography of political constituencies from the cosmopolitan urban centers to vast expanses of newly constructed suburban social landscapes. In the matter that concerns us here, this shift coincides with an increase in the ranks of college professionals across the country, simultaneous with a gravely rapid expansion in academic specialization. Second, the unprecedented development in mass media and communication technology in the so-called information age inevitably decentralizes the authority and the dissemination of knowledge, producing instead multiple points of active and direct access (Internet technology) as well as passive reception of information (television and the entertainment industry—which, in recent years, have, in economic terms at least, merged into one). This disables the effect of old intellectual centers (New York being the most celebrated), where people of learning and the world of publishing and print media were at one time organically intertwined, driving one side to retreat behind academic walls and the other to alliance with the media forces of mass entertainment culture. These new realities have given rise to a widely evoked lament for the decline of American intellectual culture.

Though such laments have historical merit, they cannot, by definition, escape the shackles of nostalgia. Under contemporary conditions, intellectuals were forced to figure new ways to participate in the proliferation of authoritative knowledge, indeed to find the proper language to engage with the contentious field of public exchange without submitting to the streamlining of ideas and the sloganeering that satisfied the commercial demands of the mass media. This necessarily produces a broader profile of knowledge than the one accounting for top reputation in
a discipline, as is the case, for example, with Noam Chomsky, who as a linguist developed an entirely new field of linguistics, yet as a public intellectual distinguished himself as a political commentator. Incidentally, it is worth noting that a 2005 Internet poll—keeping in mind all caveats over the accuracy of Internet polling—showed Chomsky to be the world’s most recognized intellectual, even though his reputation in the United States, by virtue of his politics, is much maligned. His is a case where a public intellectual achieves both stature and reputation outside his society; Chomsky’s public sphere is not so much American society but the world at large.

Yet, the Chomsky phenomenon confirms that a public intellectual must create a public, not merely conform to the parameters of the established public sphere around him. In fact, in this era of great conformism to public opinion produced, disseminated, and controlled by mass media through the voice of alleged experts, a public intellectual becomes precisely the figure who interrogates the self-confirmation and unexamined repetition of expertise, a figure whose life consists of raising critical questions “in the quest for new uncertainties” (1963, p. 16), as Richard Hofstadter (1916–1970) so memorably put it. No one, however, has made a bolder and more farseeing description of the public intellectual’s task than Edward Said (1935–2003): “This role has an edge to it, and cannot be played without a sense of being someone whose place it is publicly to raise embarrassing questions, to confront orthodoxy and dogma (rather than to produce them), to be someone who cannot be co-opted by governments or corporations, and whose raison d’être is to represent all these people and issues that are routinely forgotten or swept under the rug” (1994, p. 11). Said is exemplary, in this respect, because his global activist profile never compromised his intransigence or his rigor as a writer and a thinker, who was, moreover, unique in making the intellectual as such a subject of critical reflection.

Said adds a crucial dimension to the complex portrayal of the public intellectual in America, which is usually overlooked or not quite articulated. In conversation with the classic 1927 book by Julien Benda (1867–1956), a French rationalist conservative who decried the political irresponsibility of intellectuals whom he dubbed “clerics,” Said emphasized the quintessentially secular humanist task of the public intellectual. Even in the most committed activist practices, an intellectual’s relation to the public must necessarily resist any sort of metaphysical or aesthetistic investment. A public intellectual conceives this task neither as a prophet crying in the wilderness, in some sort of radical vanguard bearing a torch, nor as an ascetically restrained ethicist, advocating the integrity of a desiring public from the humble position of service to wisdom. The task is rather to foster a public, and indeed a public that reveres questioning authorities and identi-

ties, that shares the pleasure of disclosure, and in the end finds self-affirmation in dissent, in exercising its autonomy in the real social and political sphere.

There is, in other words, an intimate relation between whatever produces the need for public intellectuals and whatever cultivates the need, even in the darkest of times, for a real democratic politics—which must always be a politics of citizens unswayed by the pronouncements of experts, a politics of critique, self-authorization, and self-enfranchisement. Regardless of how they may articulate their personal politics, public intellectuals, by definition, must be engaged in democratic criticism, which must be uncompromising in its suspicion of pronounced authority and yet never nihilist. A public with democratic consciousness must be first and foremost a skeptical public, but nonetheless, a public committed to a vision of a future, an emancipated future. In the early twenty-first century world, where political stakes are graver than ever and political consciousness is in a state of questionable vitality, an intellectual public—however it is to be constituted—would best embody Gramsci’s inimitable call for “pesimism of the intellect and optimism of the will.”

INTELLECTUALS, VERNACULAR

As a concept that pertains to language, the vernacular has a history that dates back centuries. The concept of the vernacular intellectual is, however, of much more recent vintage. It first entered the lexicon in 2003 with Grant Farred’s work, What’s My Name?: Black Vernacular Intellectuals. Farred’s term vernacular intellectual derives from a critique of Antonio Gramsci’s (1891–1937) notion of traditional and organic intellectuals; in his famously democratic pronouncement, “all men are intellectuals,” Gramsci distinguishes between traditional and organic intellectuals (Gramsci 1972, p. 13). The former are those trained primarily as ecclesiastics, initially rooted within the medieval church; the latter are those who locate themselves more firmly within the political apparatuses of their society—thinkers organic to their class, their political party, or the state bureaucracy.

The vernacular intellectual represents a reconsideration of the category intellectual. It is premised on the critical expansion of the category in that it proposes that the work of thinking assumes many guises and cannot be restricted to the formally educated classes. According to this reconception, the vernacular intellectual is an individual whose interventions into how a society thinks about itself—its politics, race, justice—are significant in part because of the person’s identity and position. The vernacular intellectual represents a form of critical social engagement that demonstrates the intellectuality, or thought processes, of subaltern life.

The vernacular figure redefines who is understood to be an intellectual, challenging the restriction of the term intellectual to those trained by conventional intellectual means—accredited by the university system, by café or soiree society, or by political parties. This means that the vernacular intellectual may not be widely known, or not known at all, to wider society. This is because the vernacular intellectual generally emerges from the ranks of the subaltern classes and speaks the language of those constituencies, articulating a politics that is often, but not always, incommensurable with that of dominant society. The vernacular intellectual is not necessarily a figure who espouses a radical politics. The issue of language, including how the vernacular intellectual speaks and his or her vocabulary, metaphors, and idioms, is thus critical to the construction of the vernacular intellectual.

Cultural figures such as the boxer Muhammad Ali (b. 1942), the reggae singer Bob Marley (1945–1981), the singer Grace Jones (b. 1952), the rhythm and blues singer James Brown (c. 1933–2006), and the tennis player Martina Navratilova (b. 1956) all represent, in their different articulations, the vernacular intellectual. They speak particular truths to power: about race, anti-colonialism, poverty, oppression, sexuality, and subaltern pleasure. The vernacular is, therefore, most audible in popular culture: in the music, the articulations of sportspersons, and popular expressions.

When Muhammad Ali famously declared in 1966, “I ain’t got no quarrel with them Viet Cong,” he was doing considerably more than making public his own refusal to be drafted into the U.S. military. Through this statement, Ali simultaneously critiqued America’s internal racism and its international imperialism and linked one to the other, demonstrating how the vernacular intellectual can make interventions into the public sphere in a highly idiomatic yet resonant language. The vernacular intellectual is, in essence, that cultural figure who addresses the political but whose critiques are almost never recognized as the work of an intellectual.

INTELLIGENCE

Intelligence is defined as the capacity for learning, reasoning, understanding, and similar forms of mental activity. This definition implies that the concept of intelligence is both multifaceted (i.e., reflective of many aspects of mental ability) and implicative of differences among people (i.e., reflective of degrees of capacity, ability, or aptitude among individuals). Yet this definition does not necessarily relate directly to the definition of intelligence used by scientists. In fact there is no consensus on the definition of intelligence among professionals who study it (e.g., psychologists, educators, computer scientists).

MULTIPLE DEFINITIONS

There have been multiple attempts to define intelligence. These definitions can be broadly classified into five large groups: (1) consensus definitions, (2) operational definitions, (3) task-based or psychometric definitions, (4) process-based definitions, and (5) domain definitions.
“Consensus definitions” of intelligence are typically associated with attempts of researchers in the field to consolidate a variety of points of view and produce, collectively, a comprehensive common definition. In this regard two symposia that brought together researchers in the field are important. The first symposium, which took place in 1921 under the title “Intelligence and Its Measurement: A Symposium,” focused on the abilities to learn and adapt to the environment. However, the definitions of these abilities varied. For example, the American psychologist Lewis Terman emphasized abstract thinking, whereas another American psychologist, Edward Thorndike, stressed the importance of providing good responses to questions. The second symposium, which took place in 1986, brought together a new generation of intelligence researchers (e.g., Douglas Detterman, Ulric Neisser, Robert Sternberg). By then the field of intelligence had developed markedly, having produced hundreds of research articles and books. The resulting consensus definition kept the reference to learning and adaptive abilities but expanded to include many other abilities, including meta-cognitive abilities.

Although there is still no single consensus definition of intelligence, based on the discussions at these symposia, multiple other meetings, and in the press a broad definition of intelligence includes references to lower-level processes, such as perception and attention, and higher-level processes, such as problem solving, reasoning, and decision making, with regard to learning and demonstrating adaptive behaviors in problem situations. These lower- and higher-level processes are typically referred to in two dimensions: quality and speed. Quality refers to efficacy or lack of errors, and speed refers to time while learning or solving a problem. Intelligence implies the presence of no or few errors and high speed in all processes.

“Operational definitions” of intelligence are closely linked to the concept of intelligence testing. Intelligence testing was conceived of and developed by the French psychologists Alfred Binet and Théodore Simon, who first used such a test to identify learning-impaired Parisian children in the early 1900s. The “invention” was welcomed by psychologists around the world, especially in the United States, and resulted in the development of innumerable tests of intelligence. To reflect the wealth of the research and the differential power of intelligence tests in describing individual differences, the American psychologist Edwin Boring noted in 1923 that intelligence was simply what intelligence tests test. Although obviously circular in nature, this definition of intelligence is still powerful. Researchers and practitioners often use the common metric of IQ (intelligence quotient), even though IQ typically reflects many different theoretical positions when generated by different tests of intelligence. For example, the first tests of intelligence by Binet were primarily based on sensory processes; David Wechsler’s tests (which exist in three versions spanning infancy, childhood, and adulthood) measure primary judgment skills. Then there are theory-based tests, such as the tests of Raymond Cattell, which are based on the theory of crystallized (i.e., acquired and learned over the total lifetime span) and fluid (i.e., transformable to novel materials, situations, and tasks) intelligence, and such modern tests of intelligence as the Cognitive Assessment System (by Jack Naglieri and Jagannath Prasad Das) or K-ABC (by Alan and Nadeen Kaufman), which are both based on the theories of the Soviet neuropsychologist Alexander Luria. Yet as long as a test can generate an IQ, it is assumed to measure intelligence.

“Task-based or psychometric” definitions of intelligence are associated with ideas of defining intelligence through tasks that, by agreement among researchers, call for intelligence. One of the first proponents of task-based definitions of intelligence was the American psychologist Charles Spearman (1863–1945). In the early 1900s Spearman proposed that intelligence includes a so-called general (g, or mental energy) factor and task-specific factors. The g-factor can explain the observation that indicators of performance on all intelligence tasks tend to correlate with each other (e.g., doing well on one task typically suggests strong performance on other tasks as well), whereas task-specific factors can explain why these correlations are not perfect (e.g., the performance indicators will differ on tasks that involve reading versus arithmetic). Spearman’s work had a tremendous impact on the field of intelligence: Students and followers include Cattell, Wechsler, Anne Anastasi, Detterman, Arthur Jensen, and many others. Spearman’s work also had opponents. For example, Thorndike argued for three forms of intelligence: abstract, mechanical, and social. Similarly Louis Thurstone argued that several primary mental abilities form intelligence (verbal comprehension, word fluency, number facility, spatial visualization, associative memory, perceptual speed, and reasoning). In an attempt to reconcile the theories of Spearman and Thurstone, Cattell proposed a hierarchical theory of intelligence in which lower-level abilities form two higher-order factors, fluid (reasoning with novel stimuli) and crystallized (reasoning with acquired knowledge) intelligence, which in turn contribute to the g-factor. Another opponent of Spearman’s was Joy Paul Guilford, who, developing Thurstone’s ideas, stated that intelligence can be represented by 150 abilities that result from different combinations of operations (e.g., cognition and memory), content (e.g., figural and symbolic), and products (e.g., unit and class).

“Process-based” definitions of intelligence are linked to theories that are not test or task based but, rather, capture processes involved in intelligence across tasks, domains, and tests. For example, the so-called triarchic
theory of Robert Sternberg postulates three fundamental processes underlying intelligence: (1) analytical processes, which reflect judgment of a quality of an argument; (2) practical processes, which indicate skills of adaptation to situations or environment; and (3) creative processes, which capture skills of generating new knowledge and practices. Each of these types of processes is “constructed” from three different components: (a) knowledge acquisition components, (b) performance components, and (c) metacognitive components. These componential processes can manifest themselves in any area of human functioning.

“Domain-based” definitions of intelligence are typically associated with domains of expertise. For example, Howard Gardner postulates eight dimensions of intelligence. These dimensions, to a various degree, are present in all people and are recruited when particular types of tasks are performed or in particular domains of expertise. Specifically these intelligences are (1) bodily-kinesthetic, in which sportsmen excel; (2) musical, demonstrated to a high degree by musicians; (3) interpersonal, characteristic of philosophers; (4) intrapersonal, common among politicians; (5) logical-mathematical, possessed by mathematicians; (6) naturalistic, demonstrated by scientists; (7) verbal-linguistic, characteristic of writers; and (8) visual-spatial, necessary at high levels for engineers. Another example of domain-based definitions of intelligence is the theory of emotional intelligence (developed by Peter Salovey, John Mayer, and Daniel Goleman). This theory specifies intelligence in the domain of emotional functioning as the ability to perceive, appraise, express, access, generate, and regulate emotions and feelings.

**DEVELOPMENT OF INTELLIGENCE**

The concept of IQ was developed by psychologists and statisticians in such a way that the distribution of scores remains relatively constant over a life span. IQs are compared across people, not within an individual, and are characterized by a population mean of 100 and a standard deviation of 15. Yet intelligence changes developmentally, and these changes occur in a number of ways. It is obvious that the intelligence of a one-year-old cannot be compared with the intelligence of a fifty-year-old, although their IQs can be compared. There are many developmental theories, for example those of Jean Piaget (1896–1980), that demonstrate that children reason in ways distinctly different from adults. Thus if a person had an IQ score of 110 at age one and has an IQ score of 110 at age fifty, this person’s “texture” of intelligence has changed, but his or her relative position among peers has remained constant. A few relevant observations should be noted. First, early childhood intelligence is not a good predictor of level of intelligence later in life. Second, intelligence tends to vary across a person’s life span, with a gradual increase toward middle age adulthood and a graduate decline in older ages. Third, it has been reported that in the developed world, intelligence tended to increase during the twentieth century (often called the Flynn effect), but it has appeared to stabilize or even decrease in the twenty-first century.

**ETIOLOGY OF INTELLIGENCE**

Individuals in the general population differ in their intelligence. Differences are captured by assessments of intelligence, which include both standardized tests (e.g., K-ABC) and experimental tasks (e.g., computerized tasks administered to register reaction time in response to particular stimuli). To identify the sources of these individual differences, researchers investigate the etiology (i.e., origin) of intelligence.

The etiology of intelligence is typically formulated in psychology as a question of nature and nurture: Does intelligence stem from genes (i.e., nature) or environments (i.e., nurture)? This question can be traced back to ancient times, where it was initially formulated as an “either/or” dilemma. In the early twenty-first century, however, there is a consensus that both hereditary and environmental factors play substantial and complementary roles in the development of intelligence. Two statistical coefficients are typically used to express the contributions of both genes and environments: “heritability,” which shows the amount of variation in intelligence among individuals attributable to genes, and “environmentality,” which captures the variation in intelligence attributable to environment. Both coefficients are relevant only at the level of population analyses and cannot be applied to individuals. Exciting tasks in early twenty-first century research pertain to the identification of specific genes and environments that underlie differences in intelligence. For example, it has been shown that variants in such genes as COMT (a gene responsible for the production of catechol-O-methyl transferase, an enzyme involved in the breakdown of major neurotransmitters) and BDNF (a gene responsible for the production of brain-derived neurotrophic factor, a protein involved in the biochemistry of neuronal survival, growth, and differentiation) are associated with individual differences in cognitive functioning and intelligence. It has also been shown that specific environments, such as impoverished or enriched with certain micronutrients (e.g., iodine), lead to individual differences in intellectual functioning. It is important to realize that neither genes nor environment have a deterministic impact on intelligence. The influence of both types of etiological factors, both additive and interactive, is probabilistic and takes place through the brain. Specifically there is a body of research that estab-
lishes evidence regarding which structures and pathways of the brain are associated with solving intellectual tasks and how patterns of brain activation vary among people and in different experimental conditions (e.g., sleep depleted versus deprived).

Although the majority of experts agree on the importance of both genes and environment in the etiology of intelligence, there are still leftovers of the raucous debate of the early 1990s related to the arguments put forth in The Bell Curve. Written by the psychologist Richard Herrnstein and the geneticist Charles Murray, The Bell Curve claimed IQ is hereditary and, as such, the single determinant of a person’s life outcomes. That and similar debates indicate that the concept of intelligence remains a point of disagreement with the capacity to raise charged social issues.

The concept of intelligence is viewed by some as a social construct developed to capture individual differences in cognitive functioning and as such has no “permanent” definition or understanding; both vary with the change of societal context. Thus yet another disagreement in the literature on intelligence pertains to the debate of a “social” versus “real” phenomenon. Those who argue that the concept of intelligence is a social construct suggest it was invented by the privileged classes to maintain their privilege. Those who argue that the concept of intelligence is based on the latent ability truly differentiating people maintain it is a helpful differentiating and predictive concept that has value in decisions pertaining to education and job placement.

GROU P DIFFERENCES IN INTELLIGENCE

Four types of differences are typically discussed in the study of intelligence: sex differences, ethnic and racial differences, cultural differences, and differences in conditions (i.e., intelligence in deaf and hard of hearing versus in hearing people). Males and females tend to demonstrate equivalent or comparable average scores on tests of intelligence. Yet although there are no differences in performance when performance indices are averaged across tasks, there are differences on specific tasks as well as differences in variability and range. Specifically males tend to score higher on spatial and visual tasks, among others, requiring memory, motor tasks involving aiming, and certain tasks requiring mathematical skills. Females tend to score higher on tasks requiring phonological and semantic processing, verbal production and comprehension, and fine motor skills. Broadly speaking, males demonstrate advantages in spatial reasoning, and females demonstrate advantages in verbal reasoning, but this generalized statement can be challenged by the presence and absence of sex differences on other tasks. As of the early twenty-first century there is no consensus on the profile, stability, and nature of sex differences in intelligence.

Another source of group differences in intelligence is variation in performance among different ethnic and racial groups. Group differences are typically seen on standardized tests of intelligence, especially those that rely heavily on g-theories. The differences among ethnic and racial groups demonstrate the underperformance of Hispanic Americans, Native Americans, and African Americans as compared with Asian and white Americans (of a variety of ethnic backgrounds). The differences are asystematic, meaning that the profiles of differences vary for different tasks. In other words, there is no systematic differentiation of profiles of abilities among the ethnic or racial groups. It is of special interest that the ethnic gap appears to be smaller or closed when testing is conducted using tasks from process- or domain-based theories of intelligences.

Similarly people in different cultural groups around the world demonstrate varied performances on intelligence tasks. Moreover definitions of intelligence vary across cultures as well. Thus what is considered to be “intelligent” behavior among the Luo people of Kenya is different from that of Yup’ik people of Alaska. A number of researchers have studied so-called implicit theories of intelligence—ideas about intelligence conceived by laypeople. It turns out that definitions of intelligence in the East and the West, for example, are quite different, with Eastern cultures emphasizing more social-emotional components of intelligence and Western cultures emphasizing information-processing aspects of intelligence.

Another source of group differences is the difference among people with special needs. For example, deaf people tend to score lower on tests of intelligence that call for verbal skills, but their performance on tests of spatial reasoning is similar to hearing individuals. Blind people score lower on spatial tasks (when administered in Braille), but their scores are average on verbal tasks. Thus characteristics of biological development (i.e., hormonal differences), acculturation, education, and various other peculiarities of development can all be related to group differences in intelligence. At this point there is no definitive answer to why these group differences exist.

INTELLIGENCE, SOCIAL
The term “social intelligence” is typically associated with the conception of intelligence developed by Edward Thorndike (1874–1949), a distinguished animal psychologist and a recognized founder of connectionism, a movement within the cognitive sciences attempting to explain human abilities and cognitive skills as complex emergent functions arising from the recruiting of simple elements (i.e., neurons and neuronal groups) into complex networks (i.e., neuronal networks). In the early twentieth century, Thorndike separated three types of intelligence: (1) abstract (capturing what tests of intelligence measure); (2) mechanical (related to visualizing relationships among objects and understanding how the physical world works); and (3) social intelligence (reflective of the degree of success in functioning in interpersonal situations). The notion of social intelligence was further developed in the 1920s and 1930s and referred primarily to the ability of getting along with people, but also to the ability to decode, understand, and manipulate the moods of others. In addition, during the 1920s and 1930s the first tests of social intelligence were developed. The George Washington Social Intelligence Test included, for example, tests of Judgment in Social Situations, Memory for Names and Face, Observation of Human Behavior, and Sense of Humor. Yet, the concept of testing for social intelligence was not uniformly accepted: Psychologist David Wechsler, for example, argued that social intelligence is a manifestation of general intelligence in its application to social situations.

After a number of empirical studies failed to show construct validity of the social intelligence concept as it was measured at the beginning of the twentieth century, work on social intelligence slowed down substantially. It was not until psychologist Joy Paul Guilford developed a representation of social intelligence through various abilities in the domain of behavioral operations (i.e., all behavioral-psychological acts) in the late 1960s that interest in the “essence” of the construct resurfaced. But the concept of social intelligence was defined differently, through a number of terms, such as behavioral or social cognition (by Maureen O’Sullivan), social competence (by Martin Ford and Marie Tisak), intra- and interpersonal intelligence (by Howard Gardner), practical intelligence (by Robert Sternberg), emotional intelligence, and dimensions of personality (by Hans Eysenck). Although in modern day there is great interest in the concept of social intelligence, there is no consensus definition and no unity with regard to assessment approaches. Another source of support for the importance of the concept of social intelligence is associated with implicit studies of intelligence. In this research, people are typically asked to generate a list of traits relevant to intelligent behavior. Of interest is the observation that in the majority of all such studies, the dimension of social competence inevitably comes up as an important component of intelligent behavior.

In the late 1980s, psychologists John Kihlstrom and Nancy Cantor systematized the literature on cognition, intelligence, and personality. Kihlstrom and Cantor derived the definition of social intelligence as a person’s knowledge and expertise concerning oneself and the surrounding social world, and determinant of an individual’s approach to solving problems of social life. They proposed to classify social knowledge into two categories: (1) declarative social knowledge including abstract concepts and specific memories, which can be subdivided into context-free semantic and context-dependent episodic memories; and (2) procedural knowledge including rules and skills (cognitive and motor), which are necessary for the translation of declarative knowledge into action. Examples of sets of declarative social knowledge are social concepts of personalities, situations and groups, and individuals’ autobiographic memory. Examples of sets of procedural social knowledge are interpretive rules for understanding, processing, and representing social experience, such as establishing social causality; making inferences about other people’s behaviors, emotions, and feelings; judging likeability; implying trust; inducing and deducing responsibility; managing cognitive dissonance; and formulating and testing social hypotheses. According to Cantor and Kihlstrom, social intelligence is evoked when a person is faced with the need to solve problems of social life, in par-
ticular when faced with life tasks, current concerns, or personal projects. These problems can either be formulated by people themselves or imposed on them from outside. Using this definition, social intelligence can be judged quantitatively (i.e., high or low) only through the eyes of the beholder, that is, from the point of view of the person whose life is in play.

Stephen Greenspan includes social intelligence, along with practical intelligence, in his model of adaptive intelligence. In turn, adaptive intelligence, together with physical competence and socioemotional adaptation, are dimensions of personal competence. This view of social intelligence implies that it consists of three components: (1) social sensitivity (captured in social role-taking and making social inferences); (2) social insight (manifested by comprehending social situations, generating social–psychological insights, and forming ethical and moral judgments); and (3) social communication (evoked in carrying out social communication and social problem solving). This conceptualization of intelligence is important in establishing levels of mental competencies. The main argument here is that mental retardation in human societies should be defined not only based on general levels of intelligence, but also on indicators of adaptive functioning, of which social intelligence is viewed to be a major portion.

In the late twentieth and early twenty-first centuries, work on social intelligence became closely linked to research on autism. It has been argued that one of the main deficits in autism and other disorders on the autism spectrum is a lack of proper development of social intelligence or expertise in dealing with people. This line of work on social intelligence is related to the “theory of mind,” which typically refers to a specific cognitive capacity to understand that others have beliefs, desires, and intentions that are different from one’s own.

Another line of research that uses the concept of social intelligence is linked to the work on artificial intelligence (AI), which is the capacity of a digital computer or computer-controlled robot device to perform tasks commonly associated with higher intellectual processes characteristic of humans, such as the ability to reason, discover meaning, generalize, and learn from past experience. The foundation of this link is in the realization that although computers can be programmed successfully to carry out effectively and proficiently some complex analytical tasks (e.g., simulating human capabilities for problem solving), there are still no computer systems that match human flexibility in navigating the breadth of tasks encountered in everyday life. Through its connection with AI, social intelligence is also studied in game theory (i.e., the investigation and modeling of decision-making by multiple players attempting to maximize their return), action selection (i.e., the investigation and modeling of performing a choice between multiple parallel, competing, conflicting and overlapping goals), swarm intelligence paradigm (i.e., the investigation and modeling of complex emergent intelligent networks), and many other fields of applied mathematics, computer science, economics, and evolution.

INTERACTIONISM, SYMBOLIC
Symbolic interactionism is centrally but not exclusively concerned with the interpretive study of urban life. The American sociologist Herbert Blumer coined the term symbolic interactionism in 1937, initially using it to refer to the study of the symbols and meanings that operate
within specific social groups. He also emphasized the importance of the ideas of Charles Horton Cooley. Thirty-two years later Blumer published *Symbolic Interaction*, a book that clarifies the central ideas of the perspective, emphasizes that the origins of the approach are found in George Herbert Mead’s work (rather than in Cooley’s), and advocates the use of an eclectic set of qualitative methods without completely ruling out quantification. Blumer’s interpretation of and extension to Mead’s work also connected symbolic interactionism to the empirical interests of the Chicago school of sociology, the first major body of works specializing in urban sociology that arose during the 1920s and 1930s.

Symbolic interactionism has also retained its initial connection to the Progressive politics of the early-twentieth-century United States that were favored by many of the sociologists in Chicago during this time. Blumer’s 1969 formulation of symbolic interactionism stresses three premises and six root images. The three premises are: (1) “human beings act toward things on the basis of the meanings that the things have for them”; (2) meanings are derived from social interaction and group life; and (3) “these meanings are handled in, and modified through, an interpretive process used by the person in dealing with the things he [or she] encounters” (1969, p. 2). The six root images stress that social life is a group activity that is structured by layers of meaning. These meanings are incorporated into any group’s understanding of physical, social, and abstract objects. Group members initially learn these meanings through childhood socialization processes and, over time, each group member develops a sense of self through both role taking and the internalization of the group into his or her own identity. This activity is not a mechanical process; People remake their social worlds collaboratively and Blumer stressed that symbolic interactionists must be aware of the fact that although social interaction is regulated, routinized, and therefore stable, it is not fixed.

Blumer believed that symbolic interactionism was an alternative to three rival approaches: mainstream sociological research with its emphasis on quantification and variable analysis; the structural functionalism of Talcott Parsons; and psychoanalysis. Contemporary sociologists, notably Gary Alan Fine in his 1993 work and David Maines in 2001, argue that the symbolic interactionist perspective has been incorporated into mainstream sociology. However, according to Maines, this incorporation is not widely acknowledged and has therefore produced a fault line that runs through the discipline. Fine argued that the contemporary relationship between symbolic interactionism and contemporary sociology is unclear because symbolic interactionism has simultaneously been “fragmented, expanded, incorporated, and adopted” by sociologists of very different persuasions. In Fine’s view, symbolic interactionists themselves have become “intellectually promiscuous” (1993, p. 64).

In 1954 Manford Kuhn and his associates quantified traditional interactionist concerns, thus paving the way for contemporary quantitative studies of self and identity, notably by Peter Burke and Sheldon Stryker, both in 1980. Symbolic interactionists have also explored theoretical intersections, not only to structural functionalism and psychoanalysis, but also to semiotics, feminism, poststructuralism, and other traditions of thought. The journal *Symbolic Interaction* is a major resource for those interested in this perspective.

INTEREST, NATURAL RATE OF

Economists frequently refer to the interest rate the economy will tend toward under an equilibrium with price stability as the “natural” rate of interest. This equilibrium occurs in the long run, after any existing business cycles have played out. The natural rate of interest surfaced more than a century ago in the work of Swedish economist Knut Wicksell (1851–1926), though its prominence in mainstream economic thought has waxed and waned at different periods in time. Since the 1970s, the natural rate has taken a more central role in the study of monetary economics and is seen as one of the key ingredients in determining monetary policy.

One way to think about the natural rate of interest comes from the Keynesian IS-LM model of the macroeconomy. In this model, the interest rate adjusts to equate savings and borrowing decisions across the entire economy. Savings is determined by the level of output and there exists a rate of interest that clears the savings market for every level of output. The natural rate of interest is the interest rate where output is equal to potential output, with potential output defined as the level that results under full employment.

Figure 1 shows that the natural rate of interest is determined by the intersection of potential output and the IS curve. At the intersection, real GDP (gross domestic product) equals potential GDP, and the real interest rate equals the natural rate of interest. The IS curve represents all interest rate and output combinations that clear the savings market. This curve shows that output decreases as the real interest rate rises. This is due to the negative relationship between investment, a major component in aggregate demand, and the real rate of interest.

Yet another, more modern way of describing the natural rate of interest comes from the neoclassical growth model originally outlined in the works of Frank Ramsey (1903–1930), David Cass, and Tjalling Koopmans (1910–1985). In this model, households choose investment and consumption through time in order to maximize lifetime utility. The natural rate of interest in this model can be thought of as the rate that clears the capital market when the economy is growing at its natural steady rate. This rate turns out to depend inversely on the amount by which households value future consumption. If households value future consumption relatively less, then the natural rate of interest will be higher in order to compensate households that save and therefore give up current consumption in favor of future consumption.

In the United States and many other countries, the short-term interest rate is the primary monetary policy instrument. In particular, U.S. central bankers use the federal funds rate, the rate at which banks borrow from each other, as a tool to move interest rates and therefore the economy. As the main goals of monetary policy include price stability and output stabilization, the natural rate of interest provides an obvious benchmark for interest rate targeting. By setting the federal funds rate equal to the natural rate plus an inflation target (which could be zero), a bank is essentially trying to achieve the outcome resulting under an ideal economy. Interest rates above the natural rate tend to lower inflation, while rates below are expected to increase inflation.

Interestingly, John Maynard Keynes (1883–1946) ultimately objected to the idea of a natural rate of interest. He believed that this rate depended on the level of employment in the economy. Thus, there were several possible natural rates of interest, each associated with a different level of unemployment. Keynes preferred this idea of a “neutral rate of interest,” which describes the unique interest rate that equates savings and investment at full employment.

MEASURING THE NATURAL RATE

One of the major drawbacks in using the natural rate of interest is the inability to accurately observe or calculate it. Since the natural rate of interest can change due to persistent changes in aggregate supply or demand or even changes in the projections of federal government budget deficits, it is often hard to pin down. In addition, changes
in potential GDP can affect the natural rate of interest. Thus, measuring the natural rate of interest is not straightforward, and estimation techniques must be used. If the natural rate were actually constant over time, it could be estimated by averaging past real interest rates. Various methods have been implemented to account for the changing nature of the natural rate of interest.

Some methods involve weighting the data on past real interest rates differently. For example, one simple way would be to compute averages of past values of the interest rate while putting more weight on more recent data. Despite the differential weighting, this simple method does not work well during periods of large increases or decreases in inflation—when the real interest deviates substantially from the natural rate.

More sophisticated economic models have been used to measure the natural rate of interest. These include estimating the location of the slope of the IS curve and potential output to obtain estimates of interest rates. An important statistical technique known as the Kalman filter is used in some economic models to estimate the natural rate of interest. It works by adjusting the estimate of the natural rate based on how far off the model’s prediction of output is from actual output. If actual output is higher than the prediction from the model, one possible explanation is that monetary policy was more expansionary than expected, which implies that the difference between the real federal funds rate and the natural rate of interest is more negative than expected. The estimate of the natural rate then increases by an amount proportional to the prediction error. This method allows for changes in the natural rate. The estimate of the natural rate by Thomas Laubach and John C. Williams (2003) using the Kalman filter technique was 3 percent in 2002, which is not far from the average of the historical federal funds rates. However, the estimate has varied from 1 percent in the 1990s to over 5 percent in the 1960s.

Despite its intuitive appeal, monetary policy analysis involving the natural rate of interest has serious drawbacks. There is no single agreed-upon method of estimating the natural rate, and estimates can be sensitive to the statistical method used to measure it. Nonetheless, the natural rate of interest is still an important concept for evaluating monetary policy, and central banks continue to devote attention to developing and improving estimation strategies.

**INTEREST, NEUTRAL RATE OF**

The *neutral rate of interest* is, in modern parlance, the short-term interest rate that minimizes the gap between the actual and the potential output of the economy while keeping inflation close to zero. At that interest-rate level money is considered to be neutral in the sense that monetary policy does not exert any distinct influence on economic activity other than fulfilling its primary tasks of preserving a stable value of money and safeguarding the financial system.

The concept of the neutral rate of interest provides a benchmark for modern central banking in accordance with the core model of the new neoclassical synthesis, the mainstream framework for macroeconomic policy analysis that has replaced the IS-LM model. The new synthesis is based on the concept of a natural rate of output, which is the potential output that would be realized in an equilibrium with flexible wages and prices. The corresponding natural rate of interest keeps the output gap at a minimum. In an environment with sticky wages and prices this can be achieved only if inflation is minimized, such that the stickiness does not matter. Hence the term natural rate of interest is often used as synonymous with the neutral rate. Michael Woodford’s key contribution to the new synthesis, his *Interest and Prices* (2003), is a prominent example (though it has few explicit references to neutrality).

However, caveats and objections have been raised, both to defining the neutral rate of interest in terms of inflation and output gap minimization, and to equating the neutral rate with the natural rate. The most relevant objections can be traced back to the very origin of neutral-rate concepts in Knut Wicksell’s *Interest and Prices*. 

Betty T. Tao
There is a certain rate of interest on loans which is neutral in respect to commodity prices, and tends neither to raise nor to lower them. This is necessarily the same as the rate of interest which would be determined by supply and demand if no use were made of money and all lending were effected in the form of real capital goods. It comes to much the same thing to describe it as the current value of the natural rate of interest on capital (1898, p. 102).

Wicksell's definition of neutral and natural rates of interest comprises three characteristics: price-level stability, capital market equilibrium, and the correspondence of barter lending to monetary equilibrium. The first characteristic implies zero inflation. The second characteristic requires that real investment (demand) equals saving (supply). The third characteristic is the claim that credit relations in monetary economies can be studied as if they were credit relations in economies where transactions are made in kind (in natura, hence the expression “natural rate”). A fourth characteristic, also contained in Wicksell’s Interest and Prices, is the proposition that market systems tend to gravitate toward the natural rate of interest. As the representative monetary rate of interest converges on the natural rate, it becomes neutral with respect to the level and structure of real economic activity. This proposition is at the core of postulates of the (long-run) neutrality of money and has become a defining criterion for modern natural-rate concepts (such as the natural rate of unemployment).

In the early 1930s two followers of Wicksell, Erik Lindahl and Gunnar Myrdal, demonstrated that in non-stationary monetary economies with more than one good, the expected rate of return on real investment cannot be determined independently of the monetary loan rate of interest. Hence they rejected the third characteristic of Wicksell’s definition. Lindahl, Myrdal, and August Friedrich Hayek also argued that the absence of inflation does not necessarily imply that the underlying rate of interest is neutral. Interest-rate gaps, that is, discrepancies between loan rates and the rates of return to real investment, could lead to investment activities that change the capital stock, and hence the structure and level of the production, in such a way that the price level remains unchanged. Conversely, as Lindahl pointed out, a “neutral rate of interest does not necessarily imply an unchanged price level, but rather such a development of prices as is in accordance with the expectations of the public” (1930, p. 252). Wicksell’s first characteristic of the neutral rate and key ingredient of its modern definition was thus put into doubt. On the base of all these arguments, Lindahl and Myrdal (though not Hayek) refuted Wicksell’s fourth characteristic, the gravitational force of the natural rate. They argued that the equilibrium rate of return to real investment is influenced by past monetary policy through the latter’s effect on market rates of interest and capital valuation. Thus money is not automatically neutral.

The only characteristic of Wicksell’s neutral-rate concept that survived the scrutiny of Lindahl and Myrdal was the criterion of capital market equilibrium in the sense of planned investment equaling planned saving. Even this criterion came under attack when the English economist John Maynard Keynes published his The General Theory of Employment, Interest and Money (1936). In Keynes’ system, as in the conventional IS-LM framework that was subsequently developed from it, the market rate of interest does not coordinate investment with saving ex ante, but saving adjusts to investment ex post, through the latter’s multiplier effect on income. Saving thus equals investment at different levels of interest and income, and Keynes concluded that there is no unique “natural” or equilibrium rate of interest. The only rate of interest that is “unique and significant … must be the rate which we might term the neutral rate of interest, namely, the natural rate … which is consistent with full employment” (1936, p. 243). More strictly defined, the neutral rate of the interest is the rate that “prevails in equilibrium when output and employment are such that the elasticity of employment as a whole is zero” (p. 243). Whether a zero elasticity of employment is identical with potential output, and whether the latter can be described by the natural rate of unemployment has been a matter of much dispute ever since the debates about the Phillips Curve, the suggestion of a trade-off between inflation and unemployment, started in the 1960s. That the old caveats concerning the neutral rate of interest are ignored in its modern definitions is not necessarily a sign of scientific progress. It is largely due to a shift toward models of intertemporal general equilibrium in terms of continuous optimization of representative agents. Such modelling strategies simply have no room for the problems in the coordination of investment and saving decisions that were at the heart of older debates about the neutral rate of interest.

Interest, Own Rate of

The concept of own rates of interest can be traced back to Irving Fisher’s *Appreciation and Interest* (1896, pp. 8ff.). It was then revived and extended by Piero Sraffa (1932) to the determination of “commodity rates of interest” on all durable assets in his critique of Friedrich August Hayek’s *Prices and Production* (1931), and subsequently taken up by John Maynard Keynes in chapter 17, “The Essential Properties of Interest and Money,” in his *General Theory of Employment, Interest and Money* (1936). There Keynes used the concept to demonstrate that the rate of interest on money plays a crucial role in setting a limit to production below full employment.

Keynes used Sraffa’s notion that for every durable commodity there is a rate of interest for it in terms of itself, as, for example, a cotton rate of interest or a wheat rate of interest. Three components enter into the own-rate of interest of assets: a physical yield or output $q$, a carrying cost $c$, and its liquidity-premium $l$. Thus $q_c + l$ is the own-rate of interest $i$, with $q$, $c$, and $l$ measured in terms of itself as the standard. These commodity rates of interest may differ between commodities, just as interest rates are likely to differ between different currency areas. For purposes of comparison, these commodity rates must be converted into a common standard of value (*numéraire*), usually money. Furthermore, one has to consider the expected rate of appreciation or depreciation of the price of a commodity $\delta_{t,s}$, in terms of money, determined on spot and forward markets. If, for example, the spot price of 100 quarters of wheat is $p_t$, the forward price in $\theta$ periods $p_{t+\theta}$, and the money rate of interest (the own-rate of interest on money) for $\theta$ periods $i_{t,\theta}$, then the own rate of interest of wheat between $t$ and $t + \theta$ equals $\rho_{t,\theta} = (1 + i_{t,\theta})p_t - p_{t+\theta} = (1 + i_{t,\theta})p_t - p_{t+\theta} = \frac{p_{t+\theta}}{p_t} - 1$.

If the spot price of wheat is £100, the forward price for delivery in a year hence £107, and the money rate of interest 5 percent per annum, then the own rate of interest is about −2 percent per year (see Keynes 1936, p. 223).

According to Keynes, the own rate of interest of any commodity $i$ in terms of money thus can be written as

$$i_{t,s} = \rho_{t,s} + \delta_{t,s} = q_{t,s} + l_{t,s} + \rho\delta_{t,s}.$$  

The difference between the wheat rate of interest and the money rate of interest indicates that the market for wheat is not in long-run equilibrium. Although at any moment in time there might exist as many “natural” rates of interest as there are commodities, they would not be “equilibrium” rates, as has been emphasized by Sraffa in his critique of Hayek. It is only in equilibrium that the spot and the (discounted) forward price for all commodities coincide and that “all the ‘natural’ or commodity rates are equal to one another, and to the money rate” (Sraffa 1932, p. 50), which is regarded by Sraffa as the normal rate of interest for the economy as a whole.

The latter concept has no meaning in modern general equilibrium theory of the Arrow-Debreu type, in which a complete break with the classical concern with long-period equilibria has taken place. Commodities are specified not only in physical terms, but also with regard to their date of availability. The set of intertemporal equilibrium prices consists of prices paid on current markets for commodities to be traded at a future date. Although there is some technical similarity in the calculation of own rates of interest with a multiplicity of these rates in intertemporal equilibrium, there remains the crucial difference that the concept of a long-run equilibrium, in which all rates of interest are equal in terms of the standard of value and equal to the own rate of interest of that numéraire, is missing.

In contrast to modern general equilibrium theory, there are no complete future markets in Keynes’s economics. In his *General Theory* Keynes came to the conclusion that in the long run, the economy may end up in an unemployment equilibrium, and that, in absence of rigid money wages, it is the level of the money rate of interest that rules the roost and creates a barrier to full employment. The reasons are to be found in three essential properties of money: (1) (near) zero elasticity of production, which makes it scarce because it cannot be produced privately; (2) (near) zero elasticity of substitution, a potential bottomless sink for purchasing power when money demand increases; and (3) a yield of nil with negligible carrying costs while comprising a substantial liquidity premium. This opens the way for the “liquidity trap” as the decisive cause for the money rate of interest to fall inadequately. Keynes used Sraffa’s ideas in his analysis of the determination of the volume of investment. However, it is doubtful whether Keynes fully understood Sraffa’s arguments (Kurz 2000). This is reflected in Keynes’s ambiguous use of a short-run rate of interest and a long-run equilibrium rate of interest, and in the fact that his schedule of marginal efficiency of capital cannot be independent of the rate of interest (Barens and Caspari 1997).

INTEREST, REAL RATE OF

The real rate of interest is the money rate adjusted for the loss, due to inflation, of the purchasing power of the amount lent. In short, the real rate of interest is equal to the money rate of interest less the rate of inflation. This statement is often called the Fisher equation after Irving Fisher (1867–1947), an American economist who developed it in a series of publications in the first thirty years of the twentieth century. Looking back at interest rates and inflation at the end of a period, it is possible to use statistics to calculate how the real rate of interest behaved over that period. However, what is of major interest in economics is what decision makers think real interest is going to be in the future period relevant to the decision being made. Thus, in economics, as opposed to economic history, the size of the real rate of interest is something people think will hold in the future. It cannot be measured precisely. However, if at the end of a period the Fisher equation has not held, either the inflation rate was not what was expected at the beginning of the period or people did not fully take inflation into account and suffered, at least to some extent, from what is called money illusion. This latter view was the one held by Fisher himself. In his 1930 book The Theory of Interest, he argued that the relationship between the real rate of interest, the money rate, and inflation was a long-run relationship that only held when the rate of inflation did not change much over a long period. He thought that when the rate of inflation fluctuated, the rate of interest adjusted to some extent but not by enough to compensate fully, or even largely, for the changes in the rate of inflation; Fisher squarely blamed money illusion for this.

Although the real rate of interest is normally defined by the Fisher equation, it has a large role to play in economic theory apart from any relationship between inflation and interest rates. The dominant school in economics holds that the real rate of interest is the price that brings into equality the demand and supply of savings. The demand for savings comes partly from those who want to obtain income in the future either by investing in physical capital goods or by increasing their ability and skills. Demand also comes from those who wish to consume more now, relative to their income in the future. The supply of savings comes from those who wish to consume more in the future, relative to income, than now, those who are saving to buy a capital good in the future, and those who have borrowed in the past and are paying off loans. Overall, these various components of demand and supply depend on things that only change slowly, such as demographics, the rate of productivity change, institutions, and culture. When the underlying demand for savings equals the underlying supply of savings and there is no tendency for the rate of inflation to change, the real rate of interest is called the equilibrium rate of interest. It is this rate that economists often have in mind when they are discussing real interest rates. It sums up for the community overall the degree to which future benefits and costs are discounted compared to those in the present. Depending on the context, this is called the rate of time preference or the social discount rate.

Modern economic theory assumes that money illusion is unimportant, that the economy moves quickly to a position of equilibrium, and that in equilibrium the real interest rate is stable. Taken together, these three propositions suggest that the real interest rate is less volatile than the money interest rate. However, empirical studies suggest that this is not the case and that, when the rate of inflation varies, the money interest rate adjusts less than it should if the above three propositions are correct. Given that it is the expected rate of inflation when decisions are made that is relevant, the key issue in these studies is how to measure expected inflation. Some studies use survey data. Others assume a variety of mechanisms by which
peoples’ expectations are formed and use statistical techniques to measure the expectations, determined from the past data that formed expectations. Generally these studies show that, assuming a relatively stable real interest rate, the Fisher equation does not hold. Various ingenious propositions have been put forward to explain this, but the weight of the evidence confirms Fisher’s view that money illusion has a significant role to play in the operation of the economy.

The real rate of interest is an important concept in economic theory. However, because this theory largely ignores money illusion, its relevance to economic policy is greatly reduced.

INTEREST GROUPS AND INTERESTS
In every democratic society, a plethora of interest groups seeks to influence public policy. Groups representing businesses, consumers, environmental causes, and a wide range of other concerns flock in the halls of power. Interest groups can, on the one hand, be seen as contributing positively to democratic processes by allowing different parties to state their case before government. On the other hand, they may be described as unduly affecting public policy on behalf of special interests. No matter which side of this ambivalence is emphasized, the role of such groups must be of great concern to those interested in understanding politics. Among the topics attracting particular attention are the questions of how groups attract and maintain members and how groups influence public policy.

Interest groups are conventionally defined as organizations seeking to influence public policy. They are distinguished from political parties in that they do not seek election to public office. Apart from this common ground, there are different opinions as to exactly which organizations should be categorized as interest groups. Notably, some authors include individual businesses, government institutions, as well as other types of organizations that make policy-related appeals to government. Others restrict the term to membership organizations, but accept that group members might be individuals, firms, or even other interest groups. In an attempt to clear up this confusion, Grant Jordan and his collaborators (2004) have suggested reserving the terms interest group or pressure group for organizations with members, while letting the term pressure participant refer to the wider spectrum of politically active organizations.

In discussions of interest groups, it is often fruitful to distinguish between different types of groups. Various ways of subdividing the universe of interest groups have been suggested, but among the most persistently used is the distinction between special interest groups and public interest groups. Special interest groups or sectional groups represent specific sectors of society, while public interest groups act for various causes. The latter are also referred to with the terms cause groups, idealistic groups, and citizen groups. This category encompasses both groups working for specific short-term goals and groups acting for more general causes, such as environmental protection or human rights. Whereas sectional groups typically recruit their members within the sector they represent, public interest groups are at least theoretically open to anyone supportive of group goals.

The classical approach within the study of interest groups is pluralism. Writing in the 1950s and 1960s, authors such as David Truman (1913–2003) attached great importance to groups. Pluralists portray groups as competing for influence in a relatively open political system. While resources are not seen as equally distributed among groups, it is asserted that no group is able to be consistently dominant. According to pluralists, new groups will mobilize almost automatically, provided their interests are sufficiently threatened, and these groups will counteract the influence of existing groups. Even though pluralism has come under attack from many quarters, it remains an important frame of reference in the interest group literature.

Among the important blows to pluralism was E. E. Schattschneider’s (1892–1971) ascertainment that: “The flaw in the pluralist heaven is that the heavenly chorus sings with a strong upper-class accent” (Schattschneider 1960, p. 35). Contrary to the pluralist notion of a fairly balanced group system, Schattschneider and the scholars following in his footsteps documented that the interest group system is heavily biased in favor of business interests. The most influential attack on pluralism directly tar-
geted the assumption of automatic group mobilization. In The Logic of Collective Action (1965), the economist Mancur Olson (1932–1998) argued that rational self-interested individuals will not act to achieve their group interests. According to Olson, interest groups typically work to achieve public goods. It is in the nature of such goods that nonmembers cannot be excluded from consuming the good if the group is successful in providing it. If a business group is successful in obtaining business-friendly regulation of an industry, all firms in the industry will benefit. Furthermore, in large groups the contribution of one member does not make a difference in regard to whether a group will achieve its goals or not. Every potential member would therefore be better off by saving their membership dues than by joining the group. According to this logic, it is surprising that interest groups exist at all.

Following Olson’s seminal work, much attention has been devoted to discussing how interest groups come into existence. Olson himself pointed out that interest groups might recruit members by offering selective incentives, such as cheap insurance or free magazines. Other authors have argued that groups offer their members a variety of benefits ranging from material goods over social relations to the good feelings arising from contributing to a cause one believes in. Further, the importance of entrepreneurs or patrons—private or governmental—investing in the creation of groups has been emphasized. Although numerous factors helping the creation and maintenance of groups have been identified, it is highly unlikely that the existing universe of interest groups reflects a perfect mobilization of all groups and concerns.

Once established, interest groups become active in influencing politics. In these efforts, they use different strategies. Groups can rely on insider strategies, where public decision makers are targeted directly, or they can engage in outsider strategies, where the media and citizen mobilizations are used to exert pressure on policymakers. In the U.S. literature, much effort has gone into studying the lobbying of Congress, whereas Europeans have focused more on the interaction between interest groups and the bureaucracy. Among other factors, this difference reflects cross-national variation in the importance of different lobbying activities. Apart from cross-national factors, the choice of strategy also depends on group type and on factors related to the issue at hand.

An important question in regard to interest groups is whether the political process can best be described as relatively open to different types of groups or as characterized by structured interaction by certain groups and public decision makers. In the United States, authors such as Theodore J. Lowi in The End of Liberalism (1969) pointed to the close interaction between interest groups and government agencies and the resulting accommodation of interest group demands—according to Lowi working to the detriment of liberal democracy. In Europe, many countries were even described as corporatist, indicating that the integration of interest groups into public decision making was a crucial element of the political system. Although stated in other terms, the literatures on iron triangles, policy subsystems, and policy communities share common ground with corporatism in emphasizing how policy processes are often much more structured and less open than the pluralists assumed. While this debate has attracted much scholarly attention, there is now wide-spread agreement that most societies exhibit both characteristics corresponding to the pluralist notion of competition between interest groups and more structured patterns of interaction between groups and government. The challenge is therefore to account for the causes and consequences of variation in the role of interest groups.

INTEREST RATES

In everyday language, interest is the payment, made by the borrower of a sum of money to the lender, that is in addition to the repayment of the amount borrowed. The rate
of interest is the price of loans, a critical economic variable. However, its importance extends beyond economics. Payment of interest has been a major issue in ethics, and the Jewish, Christian, and Islamic religions have all had, at least for long periods of their history, outright prohibitions on demanding interest when making loans. The dominant nature of interest varies according to the culture of the society in which it is set. For example, loans made to people who are in need and face severe hardship if they cannot get a loan are an essentially different type of transaction from loans that are made to an entrepreneur to finance business operations that are confidently expected to be profitable. This entry will concentrate on the nature and role of interest in modern market economics.

In technical economic language, interest is a payment for the use of capital, with the rate of interest the price paid for this use. Except in some specialized contexts, interest is a financial variable paid for the use of financial capital or money. Economists often talk of the rate of interest. In practice there is not one rate of interest but many, and the form of the transaction can vary from the usual. For example, one way in which banks borrow is by selling bank bills, or a promise to pay the holder of the bill a stated amount at a stated date in future. The difference between the amount paid for a bank bill and the amount the bank pays back on maturity is the interest on the loan to the bank. Also, of course, interest rates can be on loans of any length of time. Loans from overnight to ten years are common, but some are indefinite, with no commitment ever to repay the money. In addition to the amount paid for the use of capital, interest rates often incorporate a risk premium to compensate the lender for bearing the risk that the capital may not be repaid promptly or at all. The risk of most national governments defaulting is practically zero, so the interest rate they pay can be taken as a measure of the pure interest part of an interest rate.

INTEREST AND PROFITS
Since the interest rate is a financial variable, one would expect that interest rates are determined by the demand for, and supply of, loans and other financial assets. However, at least since the work of Adam Smith (1723–1790) in the late eighteenth century, the dominant view among economists has been that interest rates will tend toward a figure determined by profits. In equilibrium—that is, in a situation where there is no tendency to change—the rate of interest is equal to the rate of profit on the use of new physical capital goods. Hence, despite disturbances caused by purely financial factors, interest rates are largely determined by nonfinancial or real factors.

The modern form of the theory underlying this process is based on the work of Swedish economist Knut Wicksell (1851–1926). In his pathbreaking book *Interest and Prices* (1898), Wicksell was concerned with explaining trends in prices. Wicksell calls the interest rate fixed by financial markets the *money rate of interest*, and the interest rate determined by real factors the *natural rate of interest*. He starts with a situation in which the money rate is equal to the natural rate. Wicksell then assumes an increase in the natural rate due, say, to a new innovation increasing the productivity of capital goods. The money rate is assumed to remain unchanged. Since the new capital goods are more productive and the interest costs are unchanged, profits will increase, leading to an increased demand for new capital goods in the next period.

Like most other economists of his time, Wicksell thought that the economy was always more or less in a state where there was full employment of both labor and capital. Hence, an increased demand for new capital goods will raise their prices. The incomes of those supplying capital goods will increase, and they will spend more on consumer goods, raising the prices of consumer goods. The money rate of interest has not changed, so it is still profitable to borrow to cover any higher prices of inputs, and the whole process will continue until the banking system raises interest rates to the extent required to make the money rate equal to the natural rate. The reverse process occurs if the money rate is greater than the natural rate and causes falling prices. In both cases, equilibrium is only reached when the money rate of interest changes to be equal to the natural rate, which itself is equal to the profit rate on new capital goods.

This analysis of how a divergence between the natural and money rates of interest causes cumulative movements in prices can be adapted to explain changes in the rate of inflation from some rate widely accepted as normal. It can even include relaxation of the assumption of full employment, as long as any lapses are temporary and are automatically removed by the functioning of the economy. In this analysis, interest is the price that equates the supply of funds from net savings with the demand for funds for investment in new capital goods.

INTEREST AND MONEY
John Maynard Keynes’s (1883–1946) enormously influential *General Theory of Employment, Interest, and Money* (1936), among other things, turned the focus of interest rate theory onto financial markets. In contrast to Wicksell’s analysis, Keynes focused attention on why people want to hold money rather than other financial assets such as bonds. The reason for holding money is that it is completely liquid. One can use it immediately. Keynes listed three reasons for desiring liquidity. One is the *transaction motive* to make easy both commercial and personal exchanges. Another is the *precautionary motive* to have the ability to respond immediately to unforeseen future needs.
The last reason is the speculative motive: to try and make a profit by guessing or knowing the future better than the market as a whole. Keynes thought that the major influence on interest rates in the short run was that arising from speculation on the level of future interest rates.

Not surprisingly, given the institutional arrangements of his time, Keynes thought that the volume of money in a country was determined by the central bank. This supply of money, together with the demand for money, especially that resulting from liquidity preference, determined the rate of interest. Today, institutional arrangements are very different. The ability of financial markets to create money is determined by the demand for money, with external constraints much less important. Central banks now rely on more direct ways of influencing interest rates, mainly using changes in the interest rate they charge banks who borrow from them. Nevertheless, Keynes's emphasis on monetary factors and the allocation of assets remains important.

Fitting together the two theories by using monetary factors to explain interest rates in the short run and real influences to explain interest rates in the longer run does justice to neither theory. In both cases, the determination of the rate of interest is an integral part of the bigger whole. Keynesian economists deny the proposition that the economy trends strongly toward the full-employment position, which is a crucial part of the theory in the Wicksellian tradition. If the Keynesian view is correct and there can be continuing equilibrium at less than full employment, then causation will run more from interest rates determined in financial markets to real variables like output and capital productivity than the reverse. The different theories have very different implications for monetary policy.

INTEREST RATES AS A LINK WITH THE FUTURE
Irrespective of how it is determined, the interest rate has a crucial role to play in the allocation of new capital goods. Businesspeople will only buy new capital goods if the expected profit rate on those goods is equal to or greater than the rate of interest. The rate of interest sets the hurdle that determines which of the myriad ways in which new capital can be used are realized. Thus, the interest rate determines now what types of new capital goods there will be in the future, when the output these capital goods help to produce comes on the market.

So far this entry has not discussed the situation where the money borrowed is used to buy consumer goods, rather than capital goods. Here too the interest rate has a role to play in linking the present and the future. A person may borrow to increase current consumption because future income is expected to be greater than present income or future needs to be less than present needs. Alternatively, the borrower may give more weight to consumption in the present than to consumption in the future. The price of consuming more now is given by the interest rate. Generally, the higher the interest rate the less consumption is shifted from the future to the present, though the strength of the relationship may not be strong and for many individuals the desire to consume now may result in future consumption being discounted enough to outweigh any likely rate of interest.

Interest rates can also play a role in decisions about government expenditures and other policies, such as a tariff on imports of a particular commodity or the introduction of restrictions on logging. Cost-benefit analysis can be used to evaluate policy decisions, taking into account wider social criteria and not only narrow economic benefits and costs. There are many technical problems in estimating the various costs and benefits of a particular policy change. The one that is relevant here arises because many costs and benefits will occur in the future. In many cases, more of the costs occur in the near future compared to the benefits, so the choice of the interest rate used to discount future flows of costs and benefits has a major effect on the result. Some argue that the after-tax interest return on risk-free government bonds less the rate of inflation should be used in such analyses. Others argue that, because this is a market rate of interest, it incorporates a higher rate of discounting the future than is appropriate for a social discount rate.

MONETARY POLICY
The precise way monetary policy operates depends on the institutional arrangements of financial markets, but there is now widespread agreement that the immediate target of monetary policy is the level of interest rates. The dominant view among economists is that the underlying objective of monetary policy should be to contain inflation, often to keep it in a publicly announced target range. In Wicksellian terms, the objective is to keep the money rate close to the natural rate.

Orthodoxy also allows that, when employment is markedly below full employment, monetary policy can help hasten the return to full employment. Keynesian economists hold that, in the absence of policies to prevent it, a market economy can remain well below the full-employment level indefinitely. For them, monetary policy has a part to play in restoring full employment.

In countries with floating exchange rates, monetary policy may also be used to support the exchange rate. A freely floating exchange rate, where transactions are not constrained by any controls on capital transactions, is a very flexible price, responding quickly to changes in supply and demand. In the modern global economy, the vast
majority of foreign exchange transactions are investments in financial markets where the returns are high. The return to investing foreign funds in a country is the rate of interest obtained in the country plus the expected appreciation of the country's currency in foreign exchange markets (or less any expected depreciation). Thus, other things being equal, a rise in interest rates will lead to a higher exchange rate or prevent or reduce a fall in exchange rates if depreciation is expected. There have been clear examples of countries raising interest rates to very high levels to prevent a disastrous fall in exchange rates. Behind the scenes, use of monetary policy to support the exchange rate may be more widespread.

In the traditional story, interest rate changes affect inflation and economic activity through their influence on investment in new capital goods. The implication is that this investment is made by businesses. In fact, an interest rate change usually has a stronger direct effect on residential construction by households. It may also affect credit card usage and other forms of household debt.

A second way a change in interest rates can influence the economy is its effect on bank assets. The value of existing financial assets goes down when interest rates rise. When the values of banks' assets fall, banks are less willing to lend, and a slight or a serious credit squeeze occurs. Many economists think that the availability of credit is more important than the level of the interest rate in transmitting the effects of changes in monetary policy.

The exchange rate also has a part to play in transmitting the effects of changes in the rate of interest. If interest rates rise, the value of a country's currency will rise on foreign exchange markets. This will make imports cheaper and reduce the return to exports. The low prices for imports will help restrain inflation, and the lower returns in exporting and import-competing industries will discourage investment in these industries.

The exchange rate also has a major influence on the efficacy of monetary policy, especially in the case of small countries with many economic links to the outside world. If the exchange rate is fixed and expected to stay fixed at its current value, monetary policy relies on capital controls to stop people borrowing in foreign countries. Consequently, monetary policy is usually not effective.

On the other hand, if a country has a freely floating exchange rate, problems arise if a major depreciation of the value of its currency is expected in financial markets. In this situation, monetary policy may have to ignore its usual goals and focus solely on supporting the exchange rate.

More generally, globalization has reduced the efficacy of monetary policy. For example, if rising interest rates reduce the availability of credit from domestic sources, this will be offset to some extent by the willingness of foreigners to lend. The biggest problem is probably the risk that policy aimed at expanding economic activity by reducing interest rates may lead to expectations of a depreciation in the value of a country's currency. Some depreciation is usually helpful in these circumstances, but a large depreciation can have a serious impact, especially on the distribution of income. The desire to avoid such an impact may hamstring monetary policy in some circumstances. Nevertheless, the general view is that governments still have considerable freedom in domestic macroeconomic management, but since the efficacy of monetary policy has been reduced significantly, more reliance may have to be placed on other policies.

A different aspect of the operation of monetary policy has attracted considerable attention: its effect on the relationship between short-term and long-term interest rates. This relationship is usually called the term structure of interest rates or the yield curve. Central bank operations directly influence short-term interest rates. When the actions of the central bank raise short-term interest rates, longer-term rates may not rise much, since the rises at the short-term end of the market are often considered temporary and liable to be reversed when policy changes. Normally, interest rates rise as the term of the loan lengthens, probably due to increased uncertainty about the level of interest rates in the more distant future. Thus the yield curve slopes upward as the loan lengthens. For the reasons given above, tight monetary policy can flatten, or even invert, the yield curve. Many studies have documented a historical relationship linking a flat or inverted yield curve with a recession somewhat later. Interest has arisen in using the yield curve to predict the level of activity in the genuinely unknown future, but this is a much more difficult exercise.

INTEREST RATES, NOMINAL

The nominal rate of interest is the rate (usually per year) stated as the interest rate paid. If a lender charges fees of one sort or another, then the nominal rate is less than the actual rate of interest, where interest is defined as the price of the loan. Also, when interest is paid more than once a year, the nominal rate is less than the actual rate of interest received. For example, if money is lent at 8 percent for a year with the interest paid quarterly, 2 percent of the amount lent will be paid each quarter. Sometimes, the interest is compounded, that is, not paid but added to the principal amount and interest paid on the interest. In this case, the actual rate of interest received is approximately 8.24 percent. However, even if the interest is paid quarterly, the lender has the use of the money received and could lend it to another borrower, so that effectively the rate of interest is the same as when interest is compounded.

In many circumstances, the greatest weakness in using the nominal rate of interest in decision making is that it does not take into account the loss of purchasing power due to inflation. Thus, if in the example above there is 3 percent inflation over the year, after allowing for the loss of purchasing power the lender only receives as interest 5.24 percent of the amount lent. This figure is known as the real rate of interest and the difference between it and the nominal rate is called the inflation tax. If the loan is to the government, the inflation tax is indeed a tax. If it is to a person or institution in the private sector, it equally represents a transfer of real income from the lender to the borrower. Moreover, even if those participating in financial markets took into account the inflation tax and the rate of interest adjusted accordingly, all of the interest that the lender would receive would be subject to income tax, although part of it is not income but compensation for the loss of the purchasing power of the amount lent. It is possible to overcome to some extent these deficiencies in the nominal rate of interest by indexing the amount lent to a measure of the inflation rate, but this is not usually done.

In economic theory, the rate of interest used is usually, either implicitly or explicitly, the real rate of interest. It is assumed that the inflation tax is quickly taken into account by borrowers and lenders, and that the nominal rate of interest rises and falls more or less equally with the rate of inflation. The amounts lent and borrowed and the real incomes of lenders and borrowers are not changed, at least if the effects of income taxes are ignored. The use of the nominal rate of interest in contracts in the real world is mainly considered by theorists in the context of the effects of the taxation system on peoples’ decisions. However, in the world of this economic theory, not only does everything happen quickly, there is also perfect knowledge. In the real world, neither of these conditions holds. Empirical research shows that nominal rates do not usually adjust quickly and fully when the rate of inflation changes. Nominal rates do rise and fall with inflation to some extent, but often slowly and rarely to the full extent, at least for decades. Sometimes a rise in interest rates may even come before the rise in inflation rates. Raising interest rates is the principal weapon central banks use to combat inflation, which is usually their most important concern. The lags in monetary policy are notoriously long, and central banks sometimes make a preemptive rise in interest rates when they expect a rise in inflation. When the inflation rate is falling, the reverse could occur. However, because of their great concern about inflation, central banks are often quicker to raise rates than to reduce them.

The use of the nominal rate of interest causes inefficiencies in the operation of the economy by subsidizing borrowers at the expense of lenders. Its use in monetary policy may have undesirable consequences for the distribution of income. If the rate of inflation is stable and relatively low, these consequences are small, but the more these two conditions are broken, the more important are the consequences of using the nominal rate of interest.

INTERGENERATIONAL TRANSMISSION

In the social sciences, intergenerational transmission refers to the transfer of economic or social status across generations. These cross-generational transfers occur through a variety of means, including the inheritance of occupational status, educational attainment, earnings, and wealth. In a society marked by significant levels of intergenerational transmission, there will be a corresponding persistence in economic and social stratification, and a child’s socioeconomic outcome will be highly predictable. While immobility is not necessarily synonymous with inequality, intergenerational transmissions can generate unequal opportunities for children born into the society. Thus, the presence of intergenerational transmissions has strong implications for public policy, and many scholars have made efforts to improve the knowledge of how and to what extent these transfers exist.

RESEARCH ON LEVELS OF INTERGENERATIONAL MOBILITY

A central question in the analysis of social mobility and stratification is the extent to which advantages and disadvantages are passed from generation to generation. There is a rich history of scholarship attempting to quantify the level of intergenerational transmissions. In the 1950s sociologists improved both local data collection and mobility scales, and began to assemble intergenerational mobility tables to examine inflow and outflow percentages among different occupational classes. These classes were oftentimes highly aggregated, making it difficult to arrive at substantial conclusions on intergeneration mobility. Methodologies improved significantly in the 1960s, with the introduction of the socioeconomic index (SEI), a set of scores for occupational categories that allowed researchers to apply continuous data analysis techniques to occupational groups. In 1967 Peter Blau and Otis Dudley Duncan (creator of the SEI) published a groundbreaking work, The American Occupational Structure. In it, Blau and Duncan introduced their model of the “process of stratification,” which allowed for the multivariate testing of direct and indirect effects (such as education and family background) on the earnings of children. In isolating the effects of various factors on a child’s occupational status, Blau and Duncan found that the ratio of education effects to father’s occupation effects on a son’s current occupation is approximately 2.9 to 1, suggesting that achievement tends to be far more important than ascription in occupational outcomes.

Many scholars from around the world began to apply status-attainment models to their own intergenerational transmission analyses in the 1970s. As methodological improvements continued to be made, including the transition from multivariate linear regressions to loglinear models, a growing consensus developed that intergenerational mobility was at high levels in industrial countries. Specifically, in several Western European countries and the United States, researchers in the 1970s and 1980s consistently found intergenerational elasticity coefficients of 0.20 to 0.25 (which implies that only 20 to 25 percent of earnings gaps between groups would remain after one generation). In a 1988 address, American Economic Association president Gary Becker’s comments reflected widespread sentiments at the time: “In every country with data that I have seen … earnings strongly regress to the mean[,] … low earnings as well as high earnings are not strongly transmitted from fathers to sons.”

Yet the common belief that intergenerational mobility levels were high in industrial countries would change dramatically in the late 1980s and early 1990s. Regarding the United States, specifically, recent results for elasticity coefficients suggest that intergeneration mobility is more limited than previously thought. Gary Solon (1989) argued that the low correlation between a parent and child’s socioeconomic indicators was due to selection biases and poor data measurement in previous studies. By using an entire dataset from the Panel Study on Income Dynamics (as opposed to the numerous data omissions typical of previous research) and using a five-year average of fathers’ earnings data in lieu of the standard one-year data (to better represent lifetime earnings), Solon (1992) discovered that intergenerational elasticity coefficients rose significantly from 0.21 to 0.41. Using data from the National Longitudinal Survey, David Zimmerman (1992) arrived at a similar conclusion, and in combination these two studies provided compelling evidence that after methodological corrections, intergenerational mobility was more limited than previously thought.

Many scholars have since tried to replicate and expand on Solon and Zimmerman’s original findings, and most have arrived at an intergenerational elasticity of about 0.4 or higher for the United States. Bhashkar Mazumder (2005) argued that the usage of five-year averages on fathers’ earnings is flawed because data from such a short period of time can still reflect the effects of temporary shocks, which tend to be correlated in time. Mazumder is able to average fathers’ earnings over sixteen years using...
social security earnings histories, and finds that the intergenerational elasticity between a father and a child’s earnings is dramatically higher at 0.6. By contrast, researchers in other industrialized countries have typically found intergenerational elasticity coefficients that are less than in the United States. It is important, however, to note the difficulty of cross-country coefficient comparisons, because variations in earnings measures, age ranges, and other important study characteristics can be misinterpreted as differences between countries. Taking this issue into account, it appears that Sweden, Canada, and Finland enjoy more mobility than the United States, whereas Britain and France may be slightly worse. “American exceptionalism”—the perception that the United States is a uniquely mobile country—is largely discredited as a myth.

RESEARCH ON HOW INTERGENERATIONAL TRANSMISSIONS OCCUR

Scholarly evidence suggests that intergenerational mobility is highly limited, particularly in the United States, but why it is limited and how these outcomes are transmitted across generations is not clear. One theory that has garnered much attention is the human capital explanation, developed by Gary Becker and Nigel Tomes (1979, 1986). Becker and Tomes argue that the human capital acquired by children greatly affects their earnings outcomes, and that this capital is greatly affected by investment choices made by “utility-maximizing” families. Given a limited set of resources (time, income), parents will continue investing available resources in a child until their expected rate of return (determined by a child’s ability and earnings potential) is no better than the market rate of return on investments (i.e., interest rates). Some implications of this theory are as follows: (1) Given unlimited resources, the levels of investment in a child will be determined by the child’s ability; (2) the presence of credit constraints (in low-income families) will lead to reductions in child earnings and less intergenerational mobility. Several findings support the Becker-Tomes framework, most notably the evidence from cross-country comparisons suggesting that countries with high levels of educational subsidies (and therefore lower levels of credit constraints) tend to be associated with more intergenerational income mobility. However, as previously mentioned, cross-country comparisons are difficult given the variety of alternative explanations for differences, and it should be noted that the overall evidence on the human capital investment explanation is mixed.

A second economic explanation for the persistence in intergenerational immobility is the transfer of wealth in the form of inheritances. This explanation has received little attention due to the lack of panel data on respondents who have reached the age at which bequests are typically passed on. In studying the death records of wealthy Connecticut residents and their children, Paul Menchik (1979) found an intergenerational elasticity of 0.69 between child and parent wealth at death. This finding suggests that inheritances are highly important for the upper end of the income distribution. However, scholars have largely dismissed wealth as a major factor in overall intergenerational persistence of outcomes simply because most families do not pass along substantial inheritances. For example, according to Casey Mulligan (1997) only 2 to 4 percent of estates passed on from deaths in the United States between 1960 and 1995 were subject to inheritance taxes.

Several other avenues of intergenerational transfer deserve mention as alternative explanations of immobility, despite having received minimal scholarly attention. George Borjas (1992) alludes to the possibility of “neighborhood effects” in his assessment of the impact of parent and ethnic group successes on the wage rates and occupational statuses of first- and second-generation Americans (excluding African Americans and Native Americans). His results suggest that ethnic group effects are at least as high as parent effects on the economic successes of these immigrant children. While Borjas does not attempt to explain what underlies these group effects, several possibilities exist, including discrimination, cultural effects on behavior and personality, and unequal access to information.

If discrimination is in fact a significant explanation for intergenerational immobility, this poses a considerable challenge to a society’s claim to be a meritocracy. Indeed, scholarship since The American Occupational Structure has acknowledged the unique difficulties faced by African Americans in achieving economic and social mobility. Using data from the Panel Study on Income Dynamics, Tom Hertz (2005) finds a 25 to 30 percent difference in income between the adult income of blacks and whites who grew up in households with identical long-run average incomes, even when parental levels of education were taken into account. But is this due to discrimination, or other potentially confounding factors? For example, Dalton Conley (1999) asserts that it is not race that matters in the intergenerational transmission of poverty, but rather parental assets or the class status that is typically associated with race in America. Alternatively, Thomas Sowell (1981) argues that cultural deficiencies, not market-based discrimination, explain intergroup differences in economic success. By contrast, William Darity et al. (2002) have provided some evidence that despite sharing cultural backgrounds, black Latinos suffer discriminatory wage deficiencies relative to other Latinos, indicating that “color” matters. Overall, controversy continues over the interpretation of racial and ethnic differences. Further analysis is required to determine the extent to which a “legacy of race” is reflected in economic outcomes.
While the evidence is not definitive, research suggests that levels of economic mobility across generations are low, especially in the United States. Explanations for this persistence are inconclusive, although several possibilities, including human capital, wealth, group effects, and discrimination, have received some attention. Samuel Bowles and Herbert Gintis (2002) attempt to provide a comparison of some possible causal channels of intergenerational status transmissions in the United States, and conclude that wealth, race, and schooling are important, whereas IQ and genetics are not. Though the authors acknowledge that much of the transmission process remains unclear (at least two-fifths is still unexplained in their work), their analysis serves as a model for future research. Experts hope that continued efforts in this direction will result in a better sense of how intergenerational transmissions occur, and perhaps how social inequality can be rectified.

**INTERGROUP RELATIONS**

The study of intergroup relations has long been a staple in social science research and in particular, social psychology. More recent work has tried to determine when contact between groups is likely to result in positive outcomes (Lee et al. 2004). Events such as the 9/11 Al-Qaeda terrorist attacks in the United States, the 1994 Rwandan massacre of Tutsis, and the ongoing conflicts between Sunni and Shia Muslims in Iraq are all examples of intergroup relations gone awry.

Social psychologist Gordon Allport (1897–1967) is credited with having produced the earliest and most comprehensive research on intergroup relations. His book, *The Nature of Prejudice* (1954), has provided a foundation for the study of intergroup relations since the mid-1950s. Since that time, a great deal of research in social psychology has improved our understanding of intergroup relationships, and in particular the conditions most likely to give rise to positive contact between groups (e.g., Amir 1969; Lee et al. 2004). For example, it is now well established that dramatic shifts in population and immigration policies, technological advancements, and economic volatility, as well as the overthrow of existing political regimes, can alter the nature of relations between groups—for better and for worse.

Intergroup relations are influenced by the social identities and perceptions of groups that individual group members hold. Furthermore, the quality of intergroup relations influences group members’ group identities. Thus, there is a circular aspect to group identity processes and the quality of intergroup relations. One influences and is influenced by the other.
The potential problem for intergroup relations lies in the overarching tendency human beings have for social categorization. Because of the perceptual tendency to divide the world into separate categories (i.e., social categorization), identification with one group rather than another is almost inevitable. People engage in social categorization to bring order to a seemingly endless array of stimuli (e.g., other people) that they encounter. Thus, the process of designating someone as a member of one’s own group (i.e., the in-group) or not (i.e., a member of an out-group) is one that occurs almost automatically. When intergroup relations are harmonious, members of different groups will be less apt to emphasize differences between in-groups and out-groups. However, when there is conflict, identification with one’s group becomes stronger, out-group differences are accentuated, and intergroup conflict increases.

According to researchers Henri Tajfel and John Turner, the tendency toward social categorization is all the more problematic if, as they suggest, people are generally motivated to enhance their self-esteem by identifying with certain social groups. According to social identity theory (Tajfel and Turner 1986), people are able to enhance their self-esteem by identifying with groups that they perceive to be superior to out-groups. This theory has been used most widely as an explanation for prejudice. Prejudice generally refers to negative attitudes toward members of a group that is based solely on the fact that they are members of that group. Individuals who harbor prejudice for members of a group usually have negative impressions about each of the group’s members and tend to perceive the group members as being more similar to one another than is actually the case.

Early studies of prejudice revealed unabashed pronouncements of bigoted sentiment (LaPiere 1934; Pettigrew 1969; Hyman and Sheatsley 1956/1964). More recent work demonstrates that prejudiced attitudes in the United States have declined and become subtler. For example, whites express less prejudice toward blacks today because they are indeed less prejudiced than earlier generations, and also because it is socially unacceptable to appear prejudiced. This latter point is an important one because a large volume of research involving the use of subtle measures can detect the continuing presence of negative sentiment for members of various out-groups (e.g., Banaji and Bhasker 2000; Bargh and Chartrand 1999; Dovidio et al. 1997). Taken together, legislation, normative social pressure, and fears about retaliation have attenuated expressions of prejudice.

Though less sanguine, many contemporary social psychologists who study prejudice contend that what has replaced “old-fashioned” prejudice is a newer, more insidious form of prejudice called modern racism (McConahay et al. 1981). This form of prejudice involves the deliberate concealment of prejudiced attitudes except when in the presence of like-minded others. It is expressed in terms of opposition to race-related issues such as affirmative action and interracial marriage. The modern racist is one who attributes his or her prejudiced attitudes to reasons other than prejudice. Social psychologists have developed unobtrusive measures to assess this more contemporary form of prejudice (e.g., the Implicit Association Test).

Prejudice is usually accompanied by stereotypes. Stereotypes are cognitive structures that contain information about a person (group, place, or thing). Stereotypes influence the extent to which specific information is attended to, encoded, and subsequently retrieved. In short, stereotypes influence the processing of social information. Stereotypes are functional in that they permit the conservation of cognitive resources. By stereotyping, people are able to avoid engaging in effortful processing of social information. However, the problem with relying on these heuristics is that they neglect the variability that exists among people. When we stereotype others we ignore their individuality and impose limitations upon them. Not surprisingly, the quality and extent of intergroup relations is influenced by people’s stereotypes and the prejudice they have toward out-group members. In the context of intergroup relations, less is definitely better (i.e., less stereotyping and prejudice is associated with more positive intergroup relations). Those who study intergroup relations have tended to focus upon the negative outcomes of intergroup relations, including prejudice and discrimination.

Discrimination represents a behavioral manifestation of prejudice. It involves unjustified behavior toward a group or its members simply because of their membership in that group. As is the case with outright expressions of prejudice, civil rights legislation and social normative pressure have effectively reduced blatant forms of discrimination in recent years in the United States and in other countries (Swim et al. 1995). Nevertheless, instances of discrimination continue to be unearthed and in some cases hotly contested. For example, according to Fred Pincus (2000), unchecked discrimination in the Los Angeles Police Department and criminal justice system resulted in the 1992 beating of Rodney King. The leadership of the Los Angeles Police Department condoned antiblack behaviors, and the assault on King was symptomatic of an atmosphere that supported discriminatory behavior toward black citizens. Moreover, when the defense requested a change of venue and the trial was moved to a conservative, predominantly white community, an all-white jury acquitted the officers. This is a clear example of discrimination at the institutional level.
Institutional discrimination usually refers to the way that an institution or an organization systematically or repeatedly treats people differently because of their race (or sex). This refers to the effect of practices and policies that may at times be carried out without conscious regard to race, but which has the net effect of having an adverse impact upon a group of a people. Individuals need not be personally prejudiced for institutional discrimination to be present.

The study of intergroup relations and its correlates (i.e., social identity, stereotypes, prejudice, and discrimination) continues to be a fruitful area of inquiry for researchers and policymakers. People around the world belong to many different types of groups, and groups often exert powerful influences upon individual group members and other groups. Recent and continuing world events underscore the importance of research aimed at explicating the conditions most likely to produce favorable intergroup relations.

INTERNATIONAL ECONOMIC ORDER

The term international economic order refers to the set of proscribed rules, norms, and procedures that regulate the cross-border exchange of goods, services, and capital. While economists have persistently preached the virtues of an open economy since David Ricardo (1772–1823), leaders have been warier because of a combination of ideological concerns, domestic politics, and realpolitik.

At present, the idea of an international economic order seems inextricably linked to multilateralism. However, in the century prior to 1945, almost all of the global economic rules were established at the bilateral or unilateral level. The opening of the global economy to trade in the mid-1800s was due to the Cobden-Chevalier Treaty (1860) between France and Great Britain, and the decision to extend most-favored nation trading status to
new trading partners (Stein 1984; Lazer 1999). As for capital markets, the gold standard was a creation of British hegemony; its large domestic market and deep capital markets compelled other countries to operate by the Bank of England’s rules (Eichengreen 1996).

These arrangements were temporarily suspended during World War I (1914–1918), and then disintegrated after 1930. The British tried to sustain the pre-war order, but their economic power had waned, and the United States refused to act as a supporter of the system (Lake 1983). The interwar economic system was characterized by high tariffs and beggar-thy-neighbor policies, in which countries engaged in competitive devaluations of their currency as a means to improve their balance of trade (Kindleberger 1973).

During and after World War II (1939–1945), the United States was bound and determined to foster an international economic order that would prevent the high tariff barriers and beggar-thy-neighbor policies of the 1930s. This included a global trading system to ensure that all participating members received nondiscriminatory treatment in traded goods. To aid in trade expansion, the United States also pressed for currencies to be fixed in value relative to the dollar, which in turn could be exchanged for gold. Great Britain was reluctant to accede to this kind of regime, because it undermined the British system of imperial preferences, threatened currency runs on the war-torn European economies, and potentially constrained the autonomy of domestic policymakers.

In 1944 a conference in Bretton Woods, New Hampshire, hammered out a compromise that John Gerard Ruggie (1982) famously labeled “embedded liberalism.” The world trading system was opened, and exchange rates would be fixed. Governments, however, were still given significant policy leeway to ensure full employment policies at home.

To ensure the stability of the system, the United States endorsed and funded the creation of international financial institutions (IFIs) to monitor and enforce the international economic order. The International Monetary Fund (IMF) was designed to prevent a balance-of-payments crisis among the participating countries. The World Bank was intended to help the European economies recover from the war. In contrast to the one-country/one-vote principle of other international organizations, decision-making power in the IFIs was weighted by economic size.

The third leg of the international economic order was to be the International Trade Organization (ITO). However, the proposed institution was never created due to the U.S. Senate’s failure to ratify the Havana Charter. As a result, the General Agreement on Tariffs and Trade (GATT)—originally designed as an interim facility until the ITO came into existence—became the international regime governing trade.

The GATT was considered to be a weaker institution compared to the IFIs. Despite this gap in institutional strength, however, the trade regime yielded significant results. Between 1950 and 1970, merchandise trade levels grew at twice the rate of the global economy. In contrast, Bretton Woods was short-lived; western European countries did not make their currencies convertible until 1958, and the United States unilaterally ended the fixed exchange rate portion of the Bretton Woods agreement in 1971. At crisis junctures, the United States acted outside the IFIs to promote its stated interests, deploying greater resources in the process. In the late 1940s, for example, the resources committed to the Marshall Plan dwarfed those of the World Bank. In the mid-1990s, the United States provided its own financing to bail Mexico out of its financial crisis.

The failure of the IFIs to fulfill their intended functions was also due to the economic contradictions contained within Bretton Woods. As capital controls were removed, it became next to impossible for countries to maintain the “unholy trinity” of fixed exchange rates, open capital markets, and monetary policy autonomy (Cohen 1993). The United States also ran into the “Triffin Dilemma”—it was incapable of simultaneously increasing international liquidity while pledging to keep the dollar convertible into gold.

The collapse of Bretton Woods in 1971, the rise of the third world in the form of the Group of Seventy-Seven (G-77), and the oil shocks of the 1970s led to a bifurcated, contested international economic order. To handle exchange rates, the Group of Seven (G-7) countries (Canada, France, Germany, Italy, Japan, the United Kingdom, and the United States) supplanted the IFIs. This ad hoc arrangement proved moderately successful over the next two decades in managing the floating exchange rate system among the G-7. The IFIs found themselves bereft of their original purpose at the same time that developing countries were hit by the oil crises of the 1970s. These institutions increasingly focused their resources toward the developing world. The debt crisis of the 1980s ensured that many developing countries needed the imprimatur of the IFIs in order to secure external financing. The IMF in particular exploited the conditionality of loans to developing countries in order to affect national macroeconomic policies.

The growing reliance on official financial flows came as an important shift in economic ideas was taking place. The IFIs moved away from promoting Keynesianism and toward more neoclassical policies of balanced budgets, trade liberalization, and low inflation.
At the same time, the newly sovereign nations of the third world began to contest the market-friendly rules that underpinned embedded liberalism. A slow decline in commodity prices caused worsening terms of trade in the developing world in the 1970s, and led governments to be suspicious of the vicissitudes of market forces. Inspired by the success of the Organization of Petroleum Exporting Countries (OPEC) cartel in increasing the price of oil, these countries proposed a “new international economic order” (NIEO; Cox 1979) in the 1974 United Nations General Assembly. The NIEO included several initiatives, including orderly market arrangements to stabilize commodity prices, institutionalized forms of technology transfer, and changes in trade rules to allow the third world greater access to Organization for Economic Cooperation and Development (OECD) markets while protecting their home markets from foreign competition and the presence of multinational corporations. All of these requests were resisted by the advanced industrialized states, and the structure of IFI voting guaranteed a veto by the G-7 countries in those venues (Krasner 1985). With the debt crisis of the early 1980s, third world solidarity on the NIEO collapsed, with little achieved beyond a modest increase in UN development funds.

The end of the cold war and the rise of economic globalization expanded the assigned tasks of the IFIs to include everything from advising transition economies, to establishing common financial codes and standards, to promoting democracy, to combating corruption. The leverage of the IFIs in these issue areas, however, has been limited to countries that cannot borrow from private capital markets.

The GATT morphed into the World Trade Organization (WTO) in 1995. Although the WTO has stronger enforcement mechanisms, the rising influence of developing countries like China, India, and Brazil has threatened to paralyze its ability to expand trade further. A partial response to the gridlock within the WTO has been a proliferation of regional and bilateral trade agreements outside the WTO’s purview.

At the start of the twenty-first century, the international economic order remains relatively open for trade and finance, though there are no clear rules for migration. Increasingly, the focus of international economic negotiations has shifted to questions about business and social regulation (Braithwaite and Drahos 1999; Slaughter 2004). As China begins to challenge the United States as the economic hegemon, the stability of the current system will soon be open to question.

INTERNATIONAL MONETARY FUND

The International Monetary Fund (IMF) originated at a United Nations (UN) conference in Bretton Woods, New Hampshire, in July 1944. The IMF is thus known as a Bretton Woods institution. The forty-five governments represented at that conference decided to build an institution to facilitate economic cooperation. They hoped the existence of such an institution would help countries avoid a recurrence of the disastrous, self-interested economic policies that led to the Great Depression that began in the United States around 1929 and spread throughout the world. The principal architects of the IMF were the British economist John Maynard Keynes (1883–1946), the author of The General Theory of Employment, Interest, and Money (1936), a work that revolutionized economic theory, and the chief international economist at the U.S. Treasury Department, Harry Dexter White (1892–1948). The IMF actually came into existence in December 1945 when the first twenty-nine countries signed its Articles of Agreement. The goals of the IMF were to encourage international monetary cooperation, remove foreign-exchange restrictions, stabilize exchange rates, and facilitate a multilateral payments system between member countries.

The IMF acts as an umpire in the international market and takes action to ensure the stability of the world's financial system. Its main role in its first years was to supervise the newly established fixed exchange-rate system initiated in Bretton Woods. After the collapse of the fixed exchange rate in February 1973 and the adoption of flexible exchange rates, the IMF became more involved with member countries’ economic policies by providing advice. In the 1980s the IMF had to confront the problem of mounting foreign debt in developing countries. In the 1990s the IMF addressed the transition of former socialist countries to market capitalism, and more recently it had to assist countries facing currency crises.

The main goal of the IMF is to promote a healthy world economy. The organization’s responsibilities include: (1) promoting international monetary cooperation; (2) facilitating the expansion and balanced growth of international trade; (3) promoting exchange-rate stability; (4) assisting in the establishment of a multilateral system of payments; (5) fostering economic growth and high levels of employment; and (6) providing temporary financial assistance to countries experiencing balance-of-payments problems. The IMF also strives to reduce poverty in countries around the globe, independently and in collaboration with the World Bank and other international organizations.

The IMF had 184 member countries in 2007. With the exception of North Korea, Cuba, Liechtenstein, Andorra, Monaco, Tuvalu, and Nauru, all UN member states are members of the IMF or are represented by other member states. The IMF is headquartered in Washington, D.C., with an international staff of more than 2,500. As of March 2006, the IMF’s total quotas were $308 billion, with loans outstanding of $34 billion to seventy-five countries, of which $6 billion to fifty-six countries was on concessional terms.

The IMF is financed by quota subscriptions, the share of each member in the IMF’s total funds. The quota allocated to each IMF member determines that country’s voting power, the amount of gold or international currency or its own currency that the country initially subscribes, and its access to various borrowing facilities. A large quota offers an IMF member prestige and borrowing power because a large initial subscription provides liability to extend credit to countries that need to borrow. National quotas are periodically revised.

The IMF strives to prevent economic crises by encouraging countries to adopt what IMF directors perceive to be appropriate economic policies. The organization meets these objectives primarily through surveillance, technical assistance, and lending. Surveillance is the regular policy advice that the IMF offers once a year to each of its members. The fund conducts an in-depth analysis of each member country’s economic state of affairs. Members usually allow the publication of their IMF evaluation, supplying the information to the public. Technical assistance and training are offered, mostly free of charge, to help member countries strengthen their capacity to design and implement effective policies. Technical assistance is also offered in several economic areas, including fiscal policy, monetary and exchange-rate policies, banking, financial system supervision and regulation, and statistical collection and analysis. Financial assistance is available to help member countries correct balance-of-payments problems. Countries under financial distress are required to develop a policy program supported by IMF financing, and continued financial support is conditional on the effective implementation of the program.

Major controversies surround the role and practices of the IMF in the world economy, especially concerning the conditionality of financial support, which is provided only if recipient countries implement IMF-approved economic reforms. Indeed, in a world of mostly floating exchange rates, in contrast to the fixed exchange rates in existence when the IMF was established, it is even questionable why this institution remains in existence. The IMF has received extensive criticism from people representing the entire political spectrum, including grassroots protestors and activists objecting to IMF policies in countries subjected to “structural adjustment.” Even the Austrian economist Friedrich Hayek (1899–1992) was deeply troubled by the global “statism” practiced by the
IMF. IMF policies are implemented under the principle of “one-size-fits-all” (Stiglitz 2002, p. 141). Jeffrey Sachs, the economic advisor who encouraged transitioning economies to implement shock therapy programs, argued that “the International Monetary Fund’s view, all too often, is … based on a misunderstanding of what its own role should be” (1994, p. 504).

The principles behind IMF policies are based on what John Williamson (1990) referred to as the “Washington Consensus.” Washington, for Williamson, encompassed the World Bank and the U.S. Treasury, in addition to the IMF. Williamson identified ten policy instruments for which Washington-based institutions could muster a reasonable degree of consensus, and he summarized the content of the Washington Consensus as macroeconomic prudence, outward orientation, domestic liberalization, and free market policies. The Washington Consensus, as the set of economic policies implemented by the administrations of U.S. president Ronald Reagan (1911–2004) and British prime minister Margaret Thatcher, has been labeled a “neoliberal manifesto.” The program involves devaluation of the exchange rate, liberalization of markets where prices are regulated, privatization of public sector enterprises, contraction of public sector expenditure, and the implementation of restrictive monetary policy. There is an obvious hostility to inflation, which is strongly influenced by the effect of inflation on foreign investors (Payer 1974, p. 37). The IMF imposes these economic policies on countries in financial distress that request assistance through conditionality. Countries facing a crisis often have little alternative but to accept the terms stipulated by the IMF in order to receive assistance. Thus IMF financial support of a government program concurrently ensures obedient behavior (Payer 1974, p. 31).

Proponents of the IMF’s conditionality policy argue that the fund should not give money away for free. The IMF is a financial institution, and, like any financial institution, when it lends out money it requires borrowers to guarantee the loan that they have signed by accepting IMF-approved policies. Proponents insist that it is reasonable to stipulate that further financial support will only be released after the successful implementation of reforms. At the same time, it is not clear whether the policies enforced by the IMF have been successful. Lance Taylor argues that “a fair assessment would say that the outcomes of orthodox packages ranged to moderately successful to disastrous” (1988, p. 147). Nevertheless, the success or failure of IMF programs should not be measured by monetary criteria alone; qualitative criteria, such as socioeconomic improvements and social reforms, should also be considered in any evaluation of the IMF (Körner et al. 1986, p. 4).

INTERNATIONAL NONGOVERNMENTAL ORGANIZATIONS (INGOs)

International nongovernmental organizations (INGOs) are not-for-profit voluntary associations operating at the international, transnational, or global level, with members or participants from many countries. They bring together like-minded individuals or associations of individuals to conduct a wide variety of activities across virtually all social domains, from astronomy to football to plant biology to zoo management. Although the best-known INGOs focus on human rights (for example, Amnesty International), the environment (Friends of the Earth), disaster relief (the Red Cross), and the like, most INGOs are found in scientific, technical, business and industry, medical, and professional domains. Sizable numbers are also active in domains such as sports and recreation, development, education, women’s rights, and many others. As of 2006, more than 7,000 “conventional” INGOs were in operation, along with about 20,000 internationally oriented nongovernmental organizations of more limited scope (Union of International Associations 2006).
ORIGINS AND EXPANSION

The earliest modern INGOs appeared toward the middle of the nineteenth century. Examples include the British and Foreign Anti-Slavery Society (founded in 1839), the World’s Evangelical Alliance (1846), and the Verein Deutscher Eisenbahnverwaltungen (an association of German railroad companies, 1846). By the 1860s and 1870s new INGOs had been founded in many domains such as ophthalmology, labor, geodesy, international law, dentistry, hotel management, and so on. Hundreds of INGOs were in operation by 1900, and the first compilation of information about INGOs, the initial *Annuaire de la vie internationale*, listed 374 active organizations in 1909. Many hundreds more, across an expanding range of domains, appeared in the interwar period. Since the postwar period of rapid globalization INGO organizing has soared, with more than a hundred new organizations forming each year.

In the *Yearbook of International Organizations*, the successor to *Annuaire de la vie internationale* and the definitive source of information about INGOs, conventional INGOs are defined as (1) federations of INGOs whose members are themselves large INGOs, such as the International Scientific Union and the World Federation of Trade Unions; (2) “universal” INGOs, with members in at least sixty countries or at least thirty countries on several continents (e.g., International Union Against Cancer, Education International); (3) “intercontinental” INGOs, with members in many countries on at least two continents (e.g., American Association of Port Authorities, Suzuki Association of the Americas); and (4) “regional” INGOs, with members in many countries in one continent or region (e.g., European Association for Machine Translation, Pan African Organization for Sustainable Development). A more inclusive set of INGOs includes organizations of many different types—foundations, research centers, aid and relief organizations, advocacy groups, and so on—that are internationally oriented but are based in or operate from only one or a few countries.

Active conventional INGOs increased from 374 in 1909 to 841 in 1940, to more than 3,000 in 1972, and to more than 7,300 in 2005, with the total for INGOs of all types exceeding 27,000 in 2005 (Union of International Associations 1948–). INGO growth has been almost exponential in recent decades. The world wars interrupted INGO formation, but after each war voluntary international nongovernmental organizing immediately recovered. Most of the early INGOs were universal in scope, welcoming members from anywhere in the world and defining their goals in worldwide terms—seeking to organize, for example, all the world’s chemical engineers, literary critics, rubber producers, or science librarians. After World War II regional INGOs began to appear in large numbers (Boli and Thomas 1999). The regions at issue include not only geographical areas such as Africa or Latin America, but also cultural regions (e.g., francophone countries or the Islamic world), ecological regions (tropical forest or alpine areas), and so on. In many cases, regional organizations have arisen within the aegis of universal (global) INGOs. For example, the International Organization for Standardization promoted the creation of regional technical standards bodies for Africa, Asia, and other geographical regions, whereas the International Society for Photogrammetry and Remote Sensing has encouraged the participation of relevant regional organizations (Asian, African, Pan American, South Pacific) as associates in its global endeavors.

Most INGOs founded before World War I were based in Europe or the more developed former European colonies, and INGO participation has always been higher among citizens of developed Western countries than elsewhere. However, in the postwar period the citizens of less developed, non-Western, and non-Christian countries have rapidly increased their participation in and founding of INGOs. This greater inclusiveness has increased dissonance and conflict within INGOs, particularly with respect to issues of importance to members from poorer countries. For example, global women’s organizations have found it difficult to grapple with issues such as veiling and female genital cutting because some non-Western women’s groups embrace such practices and reject Western criticisms of them. Similarly, INGO members from outside the West often insist that social and economic rights—clean water, adequate food, basic health care—are more important than the civil and political rights that are usually championed by their Western human rights counterparts.

INGO OPERATIONS AND ACTIVITIES

INGOs are a highly disparate group of transnational organizations engaged in most arenas of human activity. As nonprofit voluntary associations, they rely primarily on donations, member fees, and voluntary labor for their operations. Their goals and activities are neither economic nor political in the usual sense. Instead, they are mostly concerned with information, communication, and practical projects to organize global domains or effect global change (Boli and Thomas 1999). Many are rule-making bodies; for example, some 200 international sports federations make worldwide rules for their respective sports, and hundreds of professional associations make global rules regarding the ethical norms that apply to their members. Some INGOs seek to solve social problems or improve living conditions; others aim to improve technology, advance knowledge, create global standards, protect
International Nongovernmental Organizations (INGOs)

threatened peoples or species, or induce states, businesses, and individuals to abide by specific norms and principles. Such activities are typical of civil society organizations at the national level, and INGOs are often seen as the core of an increasingly active global civil society (Anheier et al. 2001–) that helps temper the power struggles of states and reduce the excesses of large corporations (Florini 2000). Unlike states or corporations, most INGOs focus on the promotion of public goods and the welfare of others. Only a portion of INGOs (a quarter to a third of the total), most of which are business and industry associations, act mainly to promote the interests of their members.

A striking trend in recent decades is the increasing interconnectedness of INGOs. Empowered by advanced communication systems, especially the Internet, INGOs frequently associate in loose networks and coalitions, particularly when tackling broad global problems such as environmental degradation, poverty, human rights violations, and related issues. A prominent example is the International Campaign to Ban Landmines, a coalition of more than 1,400 INGOs that convinced states to establish the 1997 treaty outlawing the manufacture, sale, or use of antipersonnel mines. Many INGOs are only “virtual” organizations with small staffs supported by tiny budgets, serving as information clearinghouses to help coordinate other INGOs’ efforts. The most common targets of these networks and coalitions are major intergovernmental organizations (IGOs) such as the International Monetary Fund (IMF) and the World Trade Organization (WTO), which are taken to task for promoting neoliberal capitalist policies without regard for social, environmental, and cultural concerns. Large corporations are also frequent targets. INGOs insist that businesses must consider the “triple bottom line” that adds social and environmental concerns to the traditional focus on profit.

Although INGOs that criticize large companies or global governance organizations such as the IMF and WTO often have antagonistic relationships with their targets, cooperative relationships between INGOs and IGOs are increasingly common (Willets 1996). More than 2,000 INGOs have formal consultative status with the United Nations Economic and Social Council and many organizations work with UN agencies on disaster relief, development, education, health, agriculture, and other issues. INGOs are also heavily involved in the operations of technical and regulatory IGOs such as the International Telecommunication Union and the International Civil Aviation Authority. Both conflict and cooperation characterize INGO/IGO relationships at major world summits sponsored by the United Nations on matters such as the environment, human rights, and women’s issues. At these summits INGOs gather in the thousands as the voices of global civil society speaking to states about their policies and programs, and conflicts over principles and practicalities are endemic. As increasingly professionalized and expert organizations, however, INGOs are emerging as accepted partners in these global governance fora (Charnovitz 1997).

CRITICISMS OF INGOS

Because INGOs focus unwelcome attention on the behavior of powerful states, corporations, and intergovernmental organizations, they themselves are subject to attack by their targets. Critics question INGO accountability, representativeness, and transparency. They argue that, unlike political leaders, INGOs are not accountable to identifiable constituencies and their members may not belong to the groups they claim to represent; unlike democratic institutions, INGOs are not entirely open about their internal operations. Critics also charge that INGOs promote irresponsible or unrealistic economic, social, and environmental policies. INGOs respond by invoking broadly legitimated world-cultural principles, standards, and norms as sources of their authority to justify both themselves and their criticisms of powerful global actors. At issue is a global struggle for legitimacy in which INGOs continue to have the edge because they are relatively disinterested and nonpartisan.

Criticism has been especially acute since 2000 regarding large development INGOs operating in the less developed countries. Both the intended beneficiaries of development aid and outside observers take development INGOs to task for numerous failings: inadequate knowledge of the cultures and societies where they operate, reliance on abstract measures of improvement that poorly reflect local realities, insufficient autonomy from donors (especially the official development assistance agencies of powerful Western states), excessive professionalization that raises barriers between INGO officials and local NGO workers, and piecemeal specialization that misses the interconnectedness of local needs and problems. Development INGOs are caught in a double bind: If they act primarily as funders and facilitators of development projects, critics deem their efforts distant, unengaged, and superficial; if they become deeply immersed in local power and stratification structures, critics accuse them of imperialistic meddling. In either mode, they may be castigated for promoting “developmentalism”—that is, projects, policies, and forms of development that exacerbate existing inequalities and exploitation while serving the economic and political interests of Western countries. Some of the most telling critiques have come from within the development sector itself. Many development INGOs have taken such criticism to heart, searching for better ways of engaging with and relying on the peoples they intend to help, but satisfactory improvements are not
easily generated and controversy remains endemic and ubiquitous.

Most INGOs, however, are neither subject to criticism nor involved in clashes of ideology, politics, or legitimacy. They operate in relative obscurity, organizing their specialized domains with considerable autonomy and exercising remarkably effective authority at the global and regional levels.

INTERNATIONAL RELATIONS

International relations (IR) is the study of relationships among the actors of international politics. Such actors include nation-states, international organizations, non-governmental organizations, and multinational corporations. The field is also sometimes called international politics, international studies, or international affairs. In the United States, IR is a branch of political science, while it is considered its own interdisciplinary field in the European and British academy. What makes IR unique from other forms of political analysis is that international politics is characterized by anarchy—or the absence of any authority superior to the nation-state. Sovereign states are thus the primary, though not the sole, important actors in the international system, because historically states are the organizations with the legitimate authority to use force within their geographically recognized areas.

APPROACHES TO IR THEORY

IR theorists do not all share the same epistemology (ways of knowing) or methodology (analyzing what they know) for approaching the puzzles of world politics. There are generally three epistemological perspectives in the field of IR. A plurality of IR scholars are positivists, and assert that the only way to know something about the world is to approach it scientifically, by producing models that approximate the reality of international politics. These models are tested with facts in order to predict the future behavior of international actors. Interpretivists disagree with this approach, in that they do not aim to predict the behavior of international actors, but to interpret and understand the motives behind that behavior. Interpretivists see a world of intersubjective understandings and ideas to be interpreted rather than used for prediction. Post-positivists think that both interpretation and causal analysis is inappropriate, and that the theories and models developed by IR theorists could instead be used to control global populations. Post-positivists seek to emancipate oppressed groups by deconstructing the relationships and concepts taken for granted in world politics to reveal how they are not “natural” but forms of power and discipline.

Epistemology influences the methodology various scholars use. For instance, most (but not all) positivists use quantitative, statistical techniques to test their models, whereas interpretivists and post-positivists use qualitative techniques (such as discourse analysis or process tracing) to illustrate their arguments.

There are several theoretical approaches in IR, as well as substantive subfields of study, as noted below.

Realism Realist IR theorists argue that the condition of anarchy in international politics results in one motivation for state action—survival. Because power helps states ensure their own survival, state interests are defined in terms of power. This means that cooperation among states will be rare, and plans to overcome such tension will ultimately fail. Classical realists like Hans Morgenthau (1946), John Herz, Raymond Aron, and E. H. Carr conceptualized power in a variety of ways—both materially (the military, the economy, geography) and strategically (diplomacy, prestige). While much of the defining literature of classical realism was produced in the immediate decades after World War II (1939–1945), later scholars such as Anthony Lang, Richard Ned Lebow, and Michael C. Williams (2004) resurrected the critical nature of classical realist work.

Liberalism Liberalism assumes that while states operate within anarchy and are primarily self-interested, this self-interest leads to cooperation rather than conflict. Institutional liberalism posits that international organiza-
tions and regimes facilitate cooperation by reducing uncertainty among states and increasing transparency. Economic or commercial liberalism asserts that open trading systems make cooperation more likely because the benefits of trade outweigh the costs of going to war. Political liberalism assesses the likelihood of cooperation or conflict based upon the nature of a country’s political system. Political liberalism has developed into a separate research program known as democratic peace theory, which posits that democratic countries are less likely to go to war with one another because of the structural and cultural nature of democratic decision-making. Liberalism is often termed idealism, but this label is inaccurate in that all IR perspectives focus upon certain ideals over others. Yet liberalism is an admittedly more optimistic view of international politics than most other perspectives.

English School (Grotian or International Society) The English school has been a viable approach to the study of IR theory since the late 1950s and early 1960s. Representatives of this school include Herbert Butterfield, Hedley Bull, Adam Watson, R. J. Vincent, Martin Wight, and more recently Barry Buzan, Timothy Dunne, Robert Jackson, Nicholas Wheeler, and Barak Mendelsohn. The name English school refers to the location where many of the founders of the school first congregated—the London School of Economics. These scholars acknowledge the role that material forces play in international politics, but also how rules, principles, and ideas augment these material forces. Thus, while states cannot escape anarchy in their calculations with other states, certain “rules” of membership govern state relations. Therefore, international politics resembles an anarchical society where sovereignty as a principle is usually respected because states value order to ensure their survival (see Bull 2002).

Constructivism Constructivism is a sociological approach to social relations, rather than a specific theory of international politics. IR constructivists see the relations and patterns of nation-states and nonstate actors as socially constructed, or made up of intersubjectively shared ideas. Constructivists explore the manner in which identities, discourse, and rules shape and are shaped by states. They claim that states seek to do more than survive in a condition of anarchy; states also seek to socialize with other nation-states. Because ideas are intersubjectively shared among states, ideas can change and thus can set the interests of nation-states. This does not mean, however, that constructivists deny the importance of conflict. IR constructivists include such mainstream scholars as Alexander Wendt, Martha Finnemore, and Michael Barnett, as well as critical theorists such as Nicholas Onuf (1989) and Friedrich Kratochwil (1989).

Neorealism and Neoliberalism Neorealism (sometimes termed structural realism) and neoliberalism both represent attempts to develop classical realism and liberalism into scientific theories of international politics to make them more amenable to causal analysis. The defining publications—for neorealism, Theory of International Politics (1979) by Kenneth Waltz; for neoliberalism, Power and Interdependence (1977) by Robert Keohane and Joseph Nye—both attempted to develop systemic analyses of international politics. Both neorealists and neoliberaists argue that states are units that act rationally to survive in a realm of anarchy, and such a universal motive produces regular behavior that can be predicted through hypothesis testing and theoretical development similar to that found in the physical sciences. The principal disagreement between the two approaches is whether states are concerned with relative gains (i.e., how a state performs relative to other states) or absolute gains.

Foreign Policy Analysis Foreign policy analysis seeks to understand the ways in which foreign policies are enacted by individuals or small groups of decision makers. International politics, from this perspective, is grounded in decisions made by leaders and elites. This subfield of IR borrows heavily from other disciplines in social science—most notably psychology. Much of this work views elites as having, for various reasons, imperfect rational capabilities, and thus attempts to make intelligible how individuals interpret incoming information and produce decisions that result in varied and sometimes disastrous outcomes. Although much foreign policy analysis focuses on individuals, it also accommodates the influence of domestic political entities (such as parties and coalitions) and bureaucracies on the foreign policy decisions made by elites. Scholars who have shaped this approach include Richard Snyder, James Rosenau, Harold and Margaret Sprout, Margaret Hermann, Charles Hermann, Richard Herrmann, Stephen Walker, and Martha Cottam.

CRITICAL THEORY

Critical theorists seek to challenge the core concepts and “commonsense” or prevailing wisdoms of mainstream IR approaches. Such theorists posit that mainstream approaches are “problem-solving theories” that through predictive analysis seek to form solutions to the most prevalent puzzles of international politics. Critical theory, on the other hand, is meant to develop an understanding of how theories and assumptions in IR are formed in the first place—and to reveal how some of these assumptions (like the “permanence” of nation-states) might instead be responsible for much of the suffering that occurs in international politics. Several forms of critical theory are discussed below.
Poststructuralism Poststructuralism draws on the social theory of philosophers like Jacques Derrida and Michel Foucault to reveal how forces and power operate in subtle ways. Poststructuralists problematize even the idea that history is connected in any meaningful way. Notable IR post-structuralists include Richard Ashley, David Campbell, and James Der Derian.

Neo-Marxist and Gramscian Theory World-systems theory and dependency theory are forms of what is known as neo-Marxist IR. Such perspectives focus less upon states and more upon the forces of capital and production in the international economic system. Gramscian perspectives (derived from the work of early twentieth-century Italian Marxist Antonio Gramsci), defined by Robert Cox (1981) and Stephen Gill, have focused upon the ways in which social relationships work in conjunction with market forces to produce certain processes and patterns evident in the international economy. It is not enough, Gramscian scholars posit, for the forces of capital to create the inequality that exists in international politics. It is also necessary for individuals and groups to believe in the market itself—and thus such internalization (ideas plus materials) makes change much more difficult and inequality more permanent.

Feminism Feminist IR is a subset of feminist social theory. As a form of critical theory, it challenges the mainstream assumptions of IR. For instance, feminist IR scholars such as J. Ann Tickner (1992), Spike Peterson, Elizabeth Hutchings, Christine Sylvester, and Cynthia Enloe have explored the masculine assumptions (war, aggressive behavior, etc.) that underpin how the nation-state is conceptualized in IR theory.

SUBFIELDS OF INTERNATIONAL RELATIONS

All these perspectives, to varying degrees, encompass important subfields in IR. Security studies, also known as international security, focuses on threats to states and the state system that stem from the environment, health (such as pandemics like HIV-AIDS), nuclear weapons, and transnational terrorist organizations. Certain scholars in this subfield use formal modeling and game theory to understand the strategic patterns of state behavior. Civil society studies focuses upon the manner in which non-governmental organizations influence the state system. Another normative turn in IR theory has produced vibrant work on international ethics. Much of this work focuses upon phenomena such as humanitarian intervention, human rights doctrines, just war theory, genocide and ethnic conflict, and economic deprivation. The field of international political economy examines the relationships between nation-states and the international market, as well as how multinational corporations use the global economy to further their material goals. And international law remains an important subfield of interest for IR scholars. For instance, many constructivists and English school theorists have used the development of international laws to demonstrate their arguments regarding the presence of identity communities or an international society.

INTERNATIONALISM

Internationalism has a series of overlapping meanings, all of which revolve around an attempt to regulate political
life at the global level in the hopes of constructing a more peaceful order. Its most common meaning is that of a political ideology that advocates greater cooperation among nation-states in the pursuit of peace through the creation of international law and institutions. It is closely associated with international organizations such as the League of Nations and the United Nations (UN), although it is not synonymous with these organizations.

Internationalism is also a U.S. foreign policy doctrine that advocates working through international organizations. Obviously related to the first definition of internationalism, this foreign policy idea is based upon the assumption that working through such organization is beneficial to U.S. national interests, and will additionally benefit the global community.

Internationalism is also a form of cooperation advocated by socialists that assumes the eventual disappearance of the nation-state. For some, this would come only through a revolutionary process; for others it would be a gradual reformation of the international system.

Each of these forms of internationalism is premised on the assumption that peace will result only from programmatic attempts at organizing international affairs. It is thus primarily a liberal ideology, although some suggest there can be a conservative version of it as well (Holbraad 2003). The overriding goal, however, is the promotion of peace through alignment of what might otherwise be conflicting interests.

**IDEATIONAL HISTORY**

As an idea, internationalism arose from the collapse of a European, Christian institutional order (Ishay 1995). As the Christian ethicopolitical order came under strain as a result of the rise of Protestantism, the Renaissance, and then the Enlightenment, political philosophers turned toward natural law as a means by which to construct a peaceful international system. An important part of this move was the recognition that allegiance to and obligations toward political communities are not necessarily wrong, but that such allegiances and obligations need to be modified by a larger set of rules and norms that might govern relations among those communities. One of the first attempts to construct such an order came from Hugo Grotius (1583–1645), a Dutch theologian and philosopher who helped create modern international law by linking older natural theories to an emerging Renaissance interest in the historical practice of political communities. Grotius's famous *The Rights of War and Peace* (1625) proposed a theoretical foundation for governing war that reformulated the “just war” tradition and launched modern international law.

The nineteenth century saw the emergence of positivist international law, which kept the same internationalist agenda but turned to different sources for its justifications (Nardin 1998). International law became the primary focus of attempts to promote internationalism, with its insistence that states remain the central agents and its attempts to limit their ability to launch war (Koskenniemi 2002). Internationalism as a political project arose from these legal attempts to align an unwillingness to give up on the nation-state with a desire for peace.

Internationalism was also an important idea among philosophers. Immanuel Kant famously argued for methods by which the international community could avoid war (Ishay 1995). Kant’s proposal for a republican peace pact has been the foundation both of the democratic peace thesis and for internationalism. Kant argued that as more states became republics, their citizens would demand more cooperation (1795). This located internationalism within the nation, something that others sought to do during the Enlightenment and romantic periods.

A very different type of internationalism arose from the philosophy of Karl Marx. Marx’s argument that the decay of capitalism would result in the construction of communism was meant to apply not just to specific states but also to the human condition more broadly. Lenin took Marx’s ideas to a more specifically international level in his work on imperialism. These ideas were taken up by both revolutionary socialists, who argued that active attempts to overturn the nation-state and its bourgeois foundations were necessary, and reform-oriented socialists, who believed that cooperation through various international fora would lead to the collapse of the capitalist order.

**INSTITUTIONAL HISTORY**

These ideas, particularly those in the realm of international law, became more concrete at the end of the nineteenth and in the early twentieth centuries. Prior to and particularly after World War I, proponents of greater international institutional arrangements to ensure peace published a number of works (Navari 2000, Jones 2002). With the end of World War I, proposals for international institutions to moderate war came to fruition with the League of Nations. For some internationalists, the League was a concrete expression of their views, but for others it was too weak to create a truly internationalist sentiment. The failure of the United States to join the League and the abandonment of its tenets by Germany, Italy, and then Japan eviscerated it, and World War II finally forced the collapse of the League.

The end of World War II saw a resurgence of internationalism, particularly in the United States. Leading the way to the creation of a new international institution, the Americans agreed to host the newly created United Nations. Once again, some internationalists were enthusi-
astic about the new institution, but others found it wanting. The creation of the World Federalist League was an attempt to push the U.S. public, and the wider international community, toward greater forms of cooperation. Functionalisit argued that as international affairs became more complex, there would be greater need for cooperation among nations.

Coupled with the creation of the United Nations, international law exploded in the post–World War II era. The International Law Commission, a body of international lawyers exploring important issues, pushed various issues forward on the international agenda, with some becoming treaties that led to new international organizations such as the International Criminal Court. As decolonization progressed the UN General Assembly soon grew beyond its few members and passed numerous nonbinding resolutions. After the end of the cold war the UN Security Council aggressively expanded its reach, producing not just binding resolutions but also more regulations to govern wider aspects of international life.

RELATERD IDEAS
Internationalism needs to be kept separate from two related but distinct terms: cosmopolitanism and globalization. Cosmopolitanism finds its roots in antiquity, with Stoic philosophers from ancient Greece and Cicero in Rome arguing for the consideration of all persons as equal (Hayden 2006). If all were truly “citizens of the world,” war and strife for the purposes of empire or monarchical advancement were pointless. This sentiment resurfaced in various religious traditions, with Christianity and Islam both arguing for a broadly understood universal community, albeit one founded on their particular religious tenets. Cosmopolitan thinking intersected with internationalism during the Enlightenment, but internationalists such as Immanuel Kant and Jean-Jacques Rousseau did not see much point in abandoning the nation-state. Instead, they thought that republican forms of cooperation, in which states agreed to limit their sovereignty for purposes of greater cooperation, were preferable to the destruction of those states in the name of a larger international community.

Cosmopolitanism has been revived with globalization, a process by which the international economic and cultural sphere becomes more unified and interdependent. Especially among analytic philosophers interested in global justice, cosmopolitan ideas have great resonance. Again, though, internationalists find some of these proposals at odds with the current power structure of the international system, in which great powers would be loathe to abandon their position in a formally anarchic, but practically hierarchic system.

Internationalism differs from proposals for a world government, against which it was largely posited in the late nineteenth and early twentieth centuries. Worried that a world government would lead to an oppressive and unwieldy bureaucracy, internationalists hoped to keep the nation-state as a foundation, but to moderate its aggressive elements through various institutional arrangements.

Finally, within the American polity, internationalism reflects a support for a foreign policy orientation toward international institutions. Although some international economic institutions—for example, the World Trade Organization, the International Monetary Foundation, and the World Bank—are widely accepted by the U.S. foreign policy elite, the United Nations continues to generate strong debate. Neoconservatives and libertarians find the constraints imposed by the UN on the ability of the United States to run its own affairs unconscionable, whereas many Democrats and centrist Republicans find the UN and its promise of multilateralism the only real option in a world so interconnected and conflictual. Especially as U.S. power is stretched to its limits in places such as Iraq, the benefits of internationalism as a foreign policy strategy will become more influential. For those who believe in the values of the Enlightenment, such a move would be most welcome, returning the United States to its role as a leading proponent of Enlightenment theory and practice.

INTERNET
The Internet is a vast global system of interconnected technical networks made up of heterogeneous information and communication technologies. It is also a social and economic assemblage that allows diverse forms of communication, creativity, and cultural exchange at a scope and scale unknown before the late twentieth century.

The terms Internet and net are often used when discussing the social implications of new information technologies, such as the creation of new communal bonds across great distances or new forms of wealth and inequality. Such a usage is imprecise: The Internet is distinct from the applications and technologies that are built upon it, such as e-mail, the World Wide Web, online gaming, file-sharing networks, and e-commerce and e-governance initiatives. There are also many networks that are or were once distinct from the Internet, such as mobile telephone networks and electronic financial networks.

Stated more precisely, the Internet is an infrastructural substrate that possesses innovative social, cultural, and economic features allowing creativity (or innovation) based on openness and a particular standardization process. It is necessary, but not sufficient, condition for many of the social and cultural implications often attributed to it. Understanding the particularity of the Internet can be key to differentiating its implications and potential impact on society from the impacts of “information technology” and computers more generally.

HISTORY AND STRUCTURE OF THE INTERNET
The Internet developed through military, university, corporate, and amateur user innovations occurring more or less constantly beginning in the late 1960s. Despite its complexity, it is unlike familiar complex technical objects—for example, a jumbo jetliner—that are designed, tested, and refined by a strict hierarchy of experts who attempt to possess a complete overview of the object and its final state. By contrast, the Internet has been subject to innovation, experimentation, and refinement by a much less well-defined collective of diverse users with wide-ranging goals and interests.

In 1968 the Internet was known as the ARPAnet, named for its principal funding agency, the U.S. Department of Defense Advanced Research Projects Agency (ARPA). It was a small but extensive research project organized by the Information Processing Techniques Office at ARPA that focused on advanced concepts in computing, specifically graphics, time-sharing, and networking. The primary goal of the network was to allow separate administratively bounded resources (computers and software at particular geographical sites) to be shared across those boundaries, without forcing standardization across all of them. The participants were primarily university researchers in computer and engineering departments. Separate experiments in networking, both corporate and academic, were also under way during this period, such as the creation of “Ethernet” by Robert Metcalfe at Xerox PARC and the X.25 network protocols standardized by the International Telecommunications Union.

By 1978 the ARPAnet had grown to encompass dozens of universities and military research sites in the United States. At this point the project leaders at ARPA recognized a need for a specific kind of standardization to keep the network feasible, namely a common operating system and networking software that could run on all of the diverse hardware connected to the network. Based on its widespread adoption in the 1970s, the UNIX operating system was chosen by ARPA as one official platform for the Internet. UNIX was known for its portability (ability to be installed on different kinds of hardware) and extensibility (ease with which new components could be added to the core system). Bill Joy (who later cofounded Sun Microsystems) is credited with the first widespread implementation of the Internet Protocol (IP) software in a UNIX operating system, a version known as Berkeley Systems Distribution (BSD).

The Internet officially began (in name and in practice) in 1983, the date set by an ad hoc group of engineers known as the Network Working Group (NWG) as the deadline for all connected computers to begin using the Transmission Control Protocol and Internet Protocol (TCP/IP) protocols. These protocols were originally designed in 1973 and consistently improved over the ensuing ten years, but only in 1983 did they become the protocols that would define the Internet. At roughly the same time, ARPA and the Department of Defense split the existing ARPAnet in two, keeping “Milnet” for sensitive military use and leaving ARPAnet for research purposes and for civilian uses.

From 1983 to 1993, in addition to being a research network, the Internet became an underground, subcultural phenomenon, familiar to amateur computer enthusiasts, university students and faculty, and “hackers.” The Internet’s glamour was largely associated with the arcane
nature of interaction it demanded—largely text-based, and demanding access to and knowledge of the UNIX operating system. Thus, owners of the more widespread personal computers made by IBM and Apple were largely excluded from the Internet (though a number of other similar networks such as Bulletin Board Services, BITNet, and FidoNET existed for PC users).

A very large number of amateur computer enthusiasts discovered the Internet during this period, either through university courses or through friends, and there are many user-initiated innovations that date to this period, ranging from games (e.g., MUDs, or Multi-User Dungeons) to programming and scripting languages (e.g., Perl, created by Larry Wall) to precursors of the World Wide Web (e.g., WAIS, Archie, and Gopher). During this period, the network was overseen and funded by the National Science Foundation, which invested heavily in improving the basic infrastructure of fiberoptic “backbones” in the United States in 1988. The oversight and management of the Internet was commercialized in 1995, with the backing of the presidential administration of Bill Clinton.

In 1993 the World Wide Web (originally designed by Tim Berners-Lee at CERN in Switzerland) and the graphical Mosaic Web Browser (created by the National Center for Supercomputing Applications at the University of Illinois) brought the Internet to a much larger audience. Between 1993 and 2000 the “dot-com” boom drove the transformation of the Internet from an underground research phenomena to a nearly ubiquitous and essential technology with far-reaching effects. Commercial investment and applications and tools that rely on the Internet.

The key protocols, known as TCP/IP, were designed in 1973 by Vint Cerf and Robert Kahn. Other key protocols, such as the Domain Name System (DNS) and User Datagram Protocol (UDP), came later. These protocols have to be implemented in software (such as in the UNIX operating system described above) to allow computers to interconnect. They are essentially standards with which hardware and software implementations must comply in order for any type of hardware or software to connect to the Internet and communicate with any other hardware and software that does the same. They can best be understood as a kind of technical Esperanto.

The Internet protocols differ from traditional standards because of the unconventional social process by which they are developed, validated, and improved. The Internet protocols are elaborated in a set of openly available documents known as Requests for Comments (RFCs), which are maintained by a loose federation of engineers called the Internet Engineering Task Force (IETF, the successor to the Network Working Group). The IETF is an organization open to individuals (unlike large standards organizations that typically accept only national or corporate representatives) that distributes RFCs free of charge and encourages members to implement protocols and to improve them based on their experiences and users’ responses. The improved protocol then may be released for further implementation.

This “positive feedback loop” differs from most “consensus-oriented” standardization processes (e.g., those of international organizations such as ISO, the International Organization for Standardization) that seek to achieve a final and complete state before encouraging implementations. The relative ease with which one piece of software can be replaced with another is a key reason for this difference. During the 1970s and 1980s this system served the Internet well, allowing it to develop quickly, according to the needs of its users. By the 1990s, however, the scale of the Internet made innovation a slower and more difficult procedure—a fact that is most clearly demonstrated by the comparatively glacial speed with which the next generation of the Internet protocol (known as IP Version 6) has been implemented.

Ultimately, the IETF style of standardization process has become a common cultural reference point of engineers and expert users of the Internet, and has been applied not only to the Internet, but also to the production of applications and tools that rely on the Internet. The result is a starkly different mode of innovation and sharing that is best exemplified by the growth and success of so-called “free software” or “open-source software.” Many of the core applications that are widely used on the Internet are developed in this fashion (famous examples
include the Linux operating system kernel and the Apache Web Server).

**CULTURAL, SOCIAL, AND ECONOMIC IMPLICATIONS OF THE INTERNET**

As a result of the unusual development process and the nature of the protocols, it has been relatively easy for the Internet to advance around the globe and to connect heterogeneous equipment in diverse settings, wherever there are willing and enthusiastic users with sufficient technical know-how. The major impediment to doing so is the reliability (or mere existence) of preexisting infrastructural components such as working energy and telecommunications infrastructures. Between 1968 and 1993 this expansion was not conducted at a national or state level, but by individuals and organizations who saw local benefit in expanding access to the global network. If a university computer science department could afford to devote some resources to computers dedicated to routing traffic and connections, then all the researchers in a department could join the network without needing permission from any centralized state authority. It was not until the late 1990s that Internet governance became an issue that concerned governments and citizens around the world. In particular, the creation of the Internet Corporation for Assigned Names and Numbers (ICANN) has been the locus of fractious dispute, especially in international arenas. ICANN's narrow role is to assign IP numbers (e.g., 192.168.0.1) and the names they map to (e.g., www.wikipedia.org), but it has been perceived, rightly or wrongly, as an instrument of U.S. control over the Internet.

With each expansion of the Internet, issues of privacy, security, and organizational (or national) authority have become more pressing. At its outset the Internet protocols sought to prioritize control within administrative boundaries, leaving rules governing use to the local network owners. Such a scheme obviated the need for a central authority that determined global rules about access, public/private boundaries, and priority of use. With the advent of widespread commercial access, however, such local control has been severely diluted, and the possibility for individual mischief (e.g., identity theft, spam, and other privacy violations) has increased with increasing accessibility.

On the one hand, increased commercial access means a decline in local organized authority over parts of the Internet in favor of control of large segments by Internet Service Providers (ISPs) and telecommunications/cable corporations. On the other hand, as the basic infrastructure of the Internet has spread, so have the practices and norms that were developed in concert with the technology—including everything from the proper way to configure a router, to norms of proper etiquette on mailing lists and for e-mail. Applications built on top of the Internet have often adopted such norms and modes of use, and promoted a culture of innovation, of “hacking” (someone who creates new software by employing a series of modifications that exploit or extend existing code or resources, with good or bad connotations depending on the context), and of communal sharing of software, protocols, and tools.

It is thus important to realize that although most users do not experience the Internet directly, the development of the particular forms of innovation and openness that characterize the Internet also characterize the more familiar applications built on top of it, due to the propagation of these norms and modes of engineering. There is often, therefore, a significant difference between innovations that owe their genesis to the Internet and those developed in the personal computer industry, the so-called “proprietary” software industry, and in distinct commercial network infrastructures (e.g., the SABRE system for airline reservations, or the MOST network for credit card transactions). The particularity of the Internet leads to different implications and potential impact on society than the impacts of “information technology” or computers more generally.

**DIGITAL MUSIC, FILM, AND INTELLECTUAL PROPERTY**

One of the most widely discussed and experienced implications of the Internet is the effect on the culture industries, especially music and film. As with previous media (e.g., video and audio cassette recorders), it is the intersection of technology and intellectual property that is responsible for the controversy. Largely due to its “openness,” the Internet creates the possibility for low-cost and extremely broad and fast distribution of cultural materials, from online books to digital music and film. At the same time, it also creates the possibility for broad and fast violation of intellectual property rights—rights that have been strengthened considerably by the copyright act of 1976 and the Digital Millennium Copyright Act (1998).

The result is a cultural battle over the meaning of “sharing” music and movies, and the degree to which such sharing is criminal. The debates have been polarized between a “war on piracy” on the one hand (with widely varying figures concerning the economic losses), and “consumer freedom” on the other—rights to copy, share, and trade purchased music. The cultural implication of this war is a tension among the entertainment industry, the artists and musicians, and the consumers of music and film. Because the openness of the Internet makes it easier than ever for artists to distribute their work, many see a potential for direct remuneration, and cheaper and more
immediate access for consumers. The entertainment industry, by contrast, argues that it provides more services and quality—not to mention more funding and capital—and that it creates jobs and contributes to a growing economy. In both cases, the investments are protected primarily by the mechanism of intellectual property law, and are easily diluted by illicit copying and distribution. And yet, it is unclear where to draw a line between legitimate sharing (which might also be a form of marketing) and illegitimate sharing (“piracy,” according to the industry).

THE DIGITAL DIVIDE
A key question about the Internet is that of social equity and access. The term digital divide has been used primarily to indicate the differential in individual access to the Internet, or in computer literacy, between rich and poor, or between developed and developing nations. A great deal of research has gone into understanding inequality of access to the Internet, and estimates of both differential access and the rate of the spread of access have varied extremely widely, depending on methodology. It is, however, clear from the statistics that between 1996 and 2005 the rate of growth in usage has been consistently greater than 100 percent in almost all regions of the globe at some times, and in some places it has reached annual growth rates of 500 percent or more. Aside from the conclusion that the growth in access to the Internet has been fantastically rapid, there are few sure facts about differential access.

There are, however, a number of more refined questions that researchers have begun investigating: Is the quantity or rate of growth in access to the Internet larger or smaller than in the case of other media (e.g., television, print, and radio)? Are there significant differences within groups with access (e.g., class, race, or national differences in quality of access)? Does access actually enhance or change a person’s life chances or opportunities?

The implication of a digital divide (whether between nations and regions, or within them) primarily concerns the quality of information and the ability of individuals to use it to better their life chances. In local terms, this can affect development issues broadly (e.g., access to markets and government, democratic deliberation and participation, and access to education and employment opportunities); in global terms, differential access can affect the subjective understandings of issues ranging from religious intolerance to global warming and environmental issues to global geopolitics. Digital divides might also differ based on the political situation—such as in the case of the Chinese government’s attempt to censor access to politicized information, which in turn can affect the fate of cross-border investment and trade.

INTERNET, IMPACT ON POLITICS
Since the mid-1990s a new force has emerged to reshape modern society—the Internet. One aspect of society that the Internet has changed significantly is politics. In politics, the Internet has produced three types of change. The first is the way that politicians reach the voting public. Previously, politicians could only reach the public using the established media (television, radio, or newspapers and magazines) or by meeting people on the street. This is no longer the case. The second change produced by the Internet relates to the participation of the average citizen in political processes. People used to be limited to voting, sit-ins, strikes, public gatherings, letter writing, and similar types of activities, but since the advent of the Internet, many new activities have developed. The third change caused by the Internet is the creation of a whole new group of participants in the political process. Before the Internet was available, the only private groups that were
politically active were either very large, very specialized, or both; the Internet has enabled small, local groups to also participate in politics.

Politicians and their staffs can use the Internet to maintain contact with supporters and to gather new supporters. Chat rooms, blogs, and email updates are the preferred resources for maintaining contact with supporters. These allow supporters to form a community and to receive the latest news about a candidate directly. The process of drawing new supporters relies on World Wide Web (WWW) sites maintained by the candidate and his or her staff. Politicians may also gain support through blogs maintained by people not officially affiliated with the candidate, as well as through email briefs to bloggers and traditional media, search engines, and general information sources such as Wikipedia. The Internet is sufficiently important in political campaigns that by the time of the 2004 U.S. presidential election, major candidates maintained staff positions dedicated to Internet campaigning.

The ability of politicians to reach their constituents does have some drawbacks. Political opponents can employ the same technologies to undermine candidacies, as happened to Barack Obama in the presidential campaign at the end of 2006 with the release of information about his attendance at a Muslim school. In the beginning of 2007, John Edwards illustrated that candidates are also capable of damaging their own campaigns when attempting to employ blogs. Both of these incidents spread over the Internet with incredible speed. Some organizations form explicitly to use the Internet politically against politicians, as with Moveon.org's actions against President George W. Bush, while others such as PoliticsNow.com arise to inform voters. Just like organizations, individual reporters from independents like the Drudge Report to mainstream reporters from The Washington Post or The New York Times have used the Internet to present various positions.

During elections, private citizens can use the Internet to show support for preferred candidates by using the candidates' Web sites directly (including making online donations) or by visiting general sites, through which they may take part in opinion polls or contribute to blog commentary. Supporters may also visit private Internet sites supporting a candidate or even sites run by interest groups that support a slate of candidates. Although Internet voting has not yet been employed on a large scale, Arizona has experimented with limited Internet voting as far back as 2000. Beyond election-related activities, citizens can use the Internet to engage in the political process in many new ways. The U.S. Congress and some state legislatures post proposed and enacted legislation on the Internet. Interested citizens can then email a representative or senator. Some state, county, and even city governments provide Web broadcasts (webcasts) of meetings. Many big-city police departments maintain Web sites with law enforcement information and crime reports.

This information allows interested citizens to follow government activity and react quickly when appropriate. Usually, citizens communicate about politics using Web sites, email, and text messaging (also called instant messaging or IM). There have been a number of instances when people used Internet resources to come together quickly to pressure a government. For example, the Internet allowed people to organize for a large protest in the Philippines in early 2001 that forced President Joseph Estrada from power. In such cases, instant messaging can be used to gather large numbers of people so rapidly that law enforcement is too slow to respond. Such gatherings, known as flash mobs, have been known to force change in governments. Flash mobs were used by protestors during the 1999 World Trade Organization meeting in Seattle, Washington, and overwhelmed local law enforcement.

Small local groups are also able to use the Internet for political purposes. It was once necessary for groups to establish either size or significant specialization before they could influence national or international politics. The Internet has allowed smaller, more localized groups to combine their influence, tap public opinion, and take a role in both national and international politics. For example, the leaders of various organizations within the militia movement in the United States have used the Internet to connect with each other, organize jointly, disseminate propaganda, and trade techniques since the late 1990s. Examples of such efforts in other countries include the Mexican Zapatista movement, whose leaders used the Internet to garner international awareness of their situation and apply international pressure on the Mexican government during the mid- to late 1990s. Activists involved in the world environmental movement used the Internet during the June 1992 United Nations Conference on Environment and Development in Rio de Janeiro, a meeting known informally as the Earth Summit, to coordinate the activities of numerous disparate groups. During the 1992 Rio sessions, these groups organized and presented their positions to delegates using the Internet. As a result of these Internet-based efforts across national borders by small political-interest groups, the opinions of these groups were taken into account and included in the resulting international treaty. Although activities at the Rio sessions predate the Internet's arrival into mainstream political activity, it showed the potential of the then newly-emerging technology and helped to promote the early use of the Internet. Although the Internet was not sufficiently widespread for groups to reach public audiences, the environmental groups used email to communicate with technophiles in other groups and to coordinate
activities. The capacity of the Internet to influence closed totalitarian societies remains unclear, but its impact on open societies is generally accepted.

From the perspective of politicians, individual citizens, or interest groups, the Internet has changed the way in which people participate in politics by allowing them to break free from historical limitations. In the case of private citizens and small interest groups, the Internet has allowed both to gain access to the political process and political powers in a manner not previously available. The role of the Internet on politics is still developing, and research on its impact is underway.

INTERNET BUBBLE

A bubble is an unsustainable increase in the price of an asset type driven by the expectation of further price increases rather than fundamental characteristics. Bubbles are a concern of social science since they result from individual calculations about the behavior of others in society. Indeed, in his 1721 poem about the first price escalation for which the term bubble was widely used, Jonathan Swift linked the British South Sea Bubble to the “madness of the crowd” denying the fundamentals: “But as a Guinea will not pass / At Market for a Farthing more / Shewn through a multiplying Glass / Than what it allways did before” (1958, p. 255).

During a bubble, the downplaying of fundamental analysis leaves little to counterbalance the momentum of the rising price and the solidifying of interests in its preservation. Lower-quality assets rise along with higher-quality assets when fundamental characteristics are less distinguished. As suggested by John Stuart Mill in *Principles of Political Economy* (1848), assessing price becomes even more difficult when money is borrowed: “Some accident, which excites expectations of rising prices … a generally reckless and adventurous feeling prevails, which disposes people to give as well as take credit more largely than at other times, and give it to persons not entitled to it” (1899, p. 47). The most vexing feature of a bubble was captured by Alan Greenspan, the chairman of the Federal Reserve Board, when he testified in April 2000 at a Senate Banking Committee hearing that a bubble cannot be definitively identified until after the fact. The benefit of hindsight suggests that there was an Internet stock bubble as Greenspan spoke.

The Internet Bubble was set against the backdrop of rapid growth in Internet use. The 1991 invention of the World Wide Web and the 1994 release of the Netscape browser transformed a text interface into a more accessible graphical interface that propelled Internet use from about 10 percent of Americans in 1995 to 50 percent by 2000. This growth held the promise of making money and a boom of investment capital flowed into Internet enterprises, commonly referred to as “dot.coms.”

One way to generate investment dollars was by issuing stock in an Internet-related company. Upon issue, Internet stocks often experienced a dramatic rise in price. Multifold increases in price on the day of issue were common. The success of early Internet stock issues prompted additional offerings. Prices for Internet stocks continued to soar in the late 1990s.

The broad expectation of increasing Internet stock prices reduced concern for the fundamental characteristics of the individual companies whose stock price was increasing. Many of the dot.coms had never made a profit. Companies operated under the assumption that if they could generate a sizable user base by giving away their product or Web site content, they would eventually figure out how to make money. Traditional standards of longevity and profitability before issuing a stock gave way in a climate of high valuations for even fundamentally weak business models. The number of potential stock...
buyers increased with the advent of online trading in which the Internet itself reduced transaction costs for buying stocks. Many stock buyers were encouraged to borrow based on expected price increases. Investment clubs and day traders proliferated. The expectation of rising prices was strong, but not sustainable. Lacking strength in the fundamentals, Internet stocks could not avoid the ultimate spiral downward when owners began selling to take profits and later to reduce losses.

The significant presence of Internet-related companies on the Nasdaq Stock Market makes it an appropriate place for identifying the contours of the Internet Bubble. Nasdaq closing values reveal a thirty-month period in which the composite index tripled and then returned. The Nasdaq closed at 1639.19 on October 20, 1998, reached 3000 for the first time on November 3, 1999, and peaked at 5048.62 on March 10, 2000. On the decline, it had closed below 3000 by November 13, 2000, and was at 1638.80 on April 4, 2001. The deflated bubble left Internet stock values at a tiny percentage of their highs and dotted the landscape with failed companies.

The massive shift of wealth during the Internet Bubble produced winners and losers. A variety of advantages, including access to the initial offering price and reserved shares, meant that those on the inside of stock offerings were more likely to be winners than were ordinary buyers. One clear winner was Internet innovation, which was facilitated by the large amounts of capital that went to enterprises during the Internet Bubble.

INTERROGATION
Interrogation is a process that seeks to obtain information by questioning (usually direct questioning) from a person often described as either a suspect or a source. Interrogation may be conducted for a number of reasons, most commonly in pursuit of a criminal investigation or to collect intelligence concerning foreign states, terrorist groups, or other persons considered to be actual or potential threats to national security. Interrogation raises a variety of legal and ethical issues that turn upon the techniques employed. But a practical issue common to all methods of interrogation concerns the efficacy of the method deployed. This depends, in part, on the ability of the interrogator (or the interrogator's associates) to detect deception. However, it is not possible to conduct a legitimate empirical study assessing the comparative efficacy of aggressive and nonaggressive interrogation tactics. Such a study would violate accepted norms of research ethics, not to mention numerous domestic and international legal provisions. For this reason, claims of relative efficacy tend to rest on sporadic anecdotal evidence.

METHODS OF INTERROGATION
Interrogation techniques range from so-called rapport-building—which often uses conversation to gain the trust and confidence of the suspect or source—to physical or mental torture that leaves the victim with permanent physical or mental scars. Between these two extremes are a number of aggressive tactics, such as stress positions, sleep deprivation, prolonged isolation, and exposure to temperature extremes. These techniques—particularly when used in combination—often constitute cruel, inhuman, or degrading treatment in violation of international law as well as domestic legal norms. In some cases, aggressive tactics may constitute physical or mental torture, despite the absence of permanent physical injury or psychological damage. Although interrogational torture has been used (and is still used) throughout the world, public statements of experienced interrogators tend to eschew torture on the grounds that it yields unreliable results.
This is because, under pressure, suspects tend to say what they think their interrogators want to hear.

Often suspects will confess in the hope that this will ease the pressure imposed by interrogators. These are sometimes called pressed-compliant confessions (Gudjonsson 2003). Sometimes persistent pressured interrogation leads suspects to doubt their own recollections, particularly in the face of apparently confident assertions by interrogators that the suspect is guilty of a crime. There have been a number of well-documented cases in which false confessions—and, as a result, criminal convictions—were obtained following the use of high pressure interrogation tactics. One of the best-known examples, given international prominence by the Oscar-nominated film In the Name of the Father (dir. Jim Sheridan, 1993), is the case of the so-called Guildford Four. It arose out of a devastating bombing campaign conducted by the Irish Republican Army on mainland Britain in 1974. Convictions were secured largely on the basis of purported confessions, despite the defendants’ claims that they had been threatened and assaulted while in custody. The convictions were not overturned until 1989, after the defendants had spent fifteen years in prison. In 2005 the British prime minister, Tony Blair, apologized to the Guildford Four and said that they deserved to be “completely and publicly exonerated.”

Interrogators have long been interested in using pharmacological agents to overcome resistance to interrogation. In the 1950s and 1960s, the U.S. Central Intelligence Agency (CIA) ran a program known by the codename MKULTRA, established in response to reports of alleged Soviet, Chinese, and North Korean mind-control techniques. (These reports were given some credence when thirty-six American airmen shot down in the Korean War falsely confessed to a vast plot to bomb civilian targets.) The MKULTRA program involved experiments (many of which were carried out on unwitting subjects) using psychoactive drugs such as LSD and mescaline in an attempt to control or influence human behavior. Other drugs reportedly used, either in experiments or during actual counterintelligence interrogations, include scopolamine, sodium pentothal, and sodium amytal. However, there is little evidence that any so-called truth serum has ever lived up to its name or its legend in popular culture. It has been alleged that, after the terror attacks in the United States on September 11, 2001, the CIA took a renewed interest in using drugs as interrogation aids. It has also been reported that the CIA used drugs prior to interrogating (among others) Khalid Sheikh Mohammed, a senior Al-Qaeda operative who is alleged to have been the architect of the 9/11 attacks and who was captured by the United States in 2003.

LIE DETECTION
There are a variety of approaches to detecting deception in interrogation. They include analysis of verbal and nonverbal behavioral cues, analysis of the content of interrogation responses, and measurement of the physiological responses to questioning. Empirical research indicates that most people (including many professional interrogators) are unable to detect deception from demeanor. Several studies have demonstrated that accuracy is generally close to chance. However, a very small number of people have proven exceptionally prodigious in their ability to detect deception. According to psychologist Paul Ekman, these people are able to detect lies by observing microexpressions, fleeting movements of dozens of facial muscles. (Ekman has cataloged these microexpressions and taught others to recognize them [Ekman 2004].) Another approach, content-based criteria analysis, scrutinizes the contents of statements for potential evidence of truthfulness, such as superfluous detail and spontaneous self-correction.

Advances in technology often seem to promise simpler methods for detecting deception, but they usually fail to deliver. The polygraph (the so-called lie detector) relies on physiological manifestations of anxiety—changes in skin conductance, heart rate, and respiration—in order to flag deception. It is therefore not effective when the subject is a sociopath or has learned to suppress these manifestations. In addition, anxiety about being tested makes the polygraph “intrinsically susceptible to producing erroneous results” (National Research Council 2003, p. 2). A number of universities and private companies—some of which are reported to have substantial U.S. government funding—are trying to develop and promote technologies such as functional magnetic resonance imaging (fMRI), electroencephalography (EEG), and infrared spectroscopy in order to detect deception by monitoring brain activity. Since the publication of a scientific paper on fMRI-based lie detection in early 2002 (Langleben at al. 2002), there has been considerable interest in the use of fMRI in particular. Despite concerns about the artificiality of such laboratory studies and their limited application in real-world scenarios, there are reports that fMRI may have already been used in counterterrorism interrogations. Some commentators have argued that fMRI has the potential to make interrogation more humane. However, false positives create further risk of mistreatment and abuse, particularly if there is undue confidence in the ability of the new technology to screen terrorists from a pool of suspects. On the other hand, if new brain imaging technologies ultimately meet their proponents’ expectations, their impact on privacy and so-called cognitive liberty will need to be addressed.
CRIMINAL INTERROGATION AND INVESTIGATIVE INTERVIEWING

A popular approach to criminal interrogation in the United States is known as the Reid Technique, named after the late president of John E. Reid & Associates, a corporation that provides interrogation training to both public and private sectors in the United States. The Reid Technique is a nine-step process designed for use on "suspects whose guilt seems definite or reasonably certain" (Inbau et al. 2001). It commences with direct confrontation of the suspect by the investigator—who states that the suspect is considered guilty of the offense—and is intended to lead to a formal confession. Proponents of the technique advocate the use of deception, including props such as a large file containing blank sheets of paper, to create the impression that the investigator already has incriminating evidence. At various stages, the investigator evaluates the suspect's verbal and nonverbal responses. If the suspect listens attentively when he is offered a motive for the crime and a potential moral excuse, this may be taken as an indication of guilt. But if he reacts with resentment, it may be considered an indication of innocence. Critics of this approach claim that it rests on the assumption that the only method of solving many criminal investigations is by obtaining a confession from the perpetrator. They also challenge the need to use trickery, deceit, and psychological manipulation, including techniques that the general public would ordinarily consider unethical (Gudjonsson 2003).

There is considerable variation—even among Western democracies—in the legal rights accorded to suspects who are interrogated in the course of a criminal investigation. In the United States, before suspects in police custody are interrogated, they must be informed that they have the right to remain silent, that anything they say can and will be used in evidence against them, that they have the right to an attorney, and that if they cannot afford an attorney, one will be appointed for them. This is often described as the Miranda warning (while the rights themselves are referred to as Miranda rights) after the decision of the U.S. Supreme Court in Miranda v. Arizona (1966). That case made clear the necessity for the warning in order to implement and protect the privilege against self-incrimination (or the right not to be compelled to incriminate oneself) enshrined in the Fifth Amendment to the U.S. Constitution. If, following a Miranda warning, the suspect refuses to talk, the prosecution will not be permitted to comment at trial on the suspect's silence. A statement obtained by police without a Miranda warning cannot be relied upon by the prosecution in order to make its case at trial, unless the defendant contradicts that statement in his oral testimony—in which case, the statement may be used to impeach the defendant, that is, to undermine his credibility as a witness.

The Supreme Court has also made clear that suspects should not be “threatened, tricked, or cajoled into a waiver” of their Miranda rights. However, empirical studies suggest that in at least 80 percent of cases suspects do waive their rights and make a statement to the police. This may be due in part to strategies adopted by police interrogators—such as emphasizing the importance of the Miranda warning by reading it in a monotonous voice or trying to persuade the suspect that he is being offered a good opportunity to tell his story and that the interrogator is trying to help him. These strategies will not invalidate the suspect’s waiver of the Miranda rights if, taking into account all the circumstances, the court concludes that the waiver was “voluntary and intelligent.”

INTERROGATION AND THE COLLECTION OF INTELLIGENCE

The laws of war—in particular, the provisions of the Third Geneva Convention of 1949—impose strict limits on the questioning of prisoners of war. Strictly speaking, prisoners of war are only required to state their name, rank, and serial number. They must not be subjected to physical and mental torture or “any other form of coercion,” and they must be protected against “acts of violence or intimidation and against insults.” If prisoners of war refuse to answer questions during interrogation, they “may not be threatened, insulted, or exposed to any unpleasant or disadvantageous treatment of any kind.” Similar protections are also provided for civilian detainees by the Fourth Geneva Convention of 1949. The laws of war do not, however, prohibit positive inducements or incentives for responsiveness to questioning. International human rights law—which applies both in war and in times of peace—also prohibits torture and cruel, inhuman, and degrading treatment and positively requires the humane treatment of detainees.

Prior to the terrorist attacks in the United States on September 11, 2001, official U.S. Army interrogation policy and practice reflected these international norms. Army Field Manual 34-52 (1992) on interrogation states that the laws of war and U.S. policy “expressly prohibit acts of violence or intimidation, including physical or mental torture, threats, insults, or exposure to inhumane treatment as a means of or aid to interrogation.” It also states that the “use of torture and other illegal methods is a poor technique that yields unreliable results, may damage subsequent collection efforts, and can induce the source to say what he thinks the interrogator wants to hear.” After 9/11, when further attacks were anticipated and feared, more aggressive interrogation techniques were formally authorized and adopted at U.S. detention facilities in Afghanistan, Iraq, and Guantánamo Bay, Cuba. Techniques used included sleep deprivation, stress posi-
tions, prolonged isolation, and exposure to temperature extremes. (Controversially, U.S. Army psychiatrists and psychologists—attached to military intelligence and acting as behavioral science consultants—were tasked with advising interrogators as to the most effective approach for individual detainees.) Such tactics were formally justified on a number of legal grounds, among them that terrorists were not subject to the protections of the Geneva Conventions and that the international human rights obligations of the United States did not prohibit cruel, inhuman, and degrading treatment of aliens detained abroad. (It was the latter claim that the U.S. Congress intended to rebut when it passed the so-called McCain Amendment to the Defense Appropriations Bill at the end of 2005.) The U.S. government has claimed that the use of more aggressive interrogation techniques has procured valuable intelligence, but this has not been independently verified.

The publication of photographs in 2004 recording the abuse of detainees by U.S. soldiers at Abu Ghraib prison in Iraq triggered public debate in the United States and abroad about the proper limits of interrogation. These debates were further fuelled by revelations that the CIA was interrogating detainees at secret locations in eastern Europe and elsewhere (called black sites, whose existence President George W. Bush subsequently confirmed) and that the United States had handed detainees over to nations known to torture suspects (a practice described as extraordinary rendition).

In a landmark decision in June 2006, the U.S. Supreme Court held that suspected Al-Qaeda detainees are entitled to the basic protections found in Common Article 3 of the Geneva Conventions (Hamdan v. Rumsfeld 2006). At a minimum, they must be treated humanely, and protected from cruel, inhuman, and degrading treatment and from outrages on personal dignity. A few weeks later the army published a new field manual on interrogation, Field Manual 2-22.3 (2006), which prohibits interrogation tactics such as “waterboarding” (a procedure designed to simulate the experience of drowning), the hooding of detainees, and the use of barking dogs. However, this manual does not apply to detainees in the custody of the CIA, and concerns about the continuing use of aggressive interrogation tactics were fueled by two further developments.

After President Bush criticized the provisions of Common Article 3 of the Geneva Conventions for being “too vague,” Congress passed the Military Commissions Act of 2006, which purports to give the president the authority to “interpret the meaning and application of the Geneva Conventions” (Sec. 6(a)(3)). When the president signed the act into law, he noted that it would “allow the Central Intelligence Agency to continue its program for questioning key terrorist leaders and operatives” (Bush 2006). Just days later, while lawyers and commentators were debating the effect of the act on permissible interrogation strategies, Vice President Richard Cheney sparked further controversy. When asked in a radio interview if “a dunk in water is a no-brainer if it can save lives,” Mr. Cheney replied, “it’s a no-brainer for me” (Eggen 2006, p. A2). He also expressed agreement with the view that the debate over interrogation techniques was “a little silly” (Eggen 2006, p. A2).

INTERSECTIONALITY

The premise of intersectionality theory, first articulated by feminists of color, is that social differentiation is achieved through complex interactions between markers of difference such as gender, race, and class. In order to comprehend how an individual’s access to social, political, and economic institutions is differentially experienced, it is necessary to analyze how markers of difference intersect and interact.

In the 1970s feminist theory could be divided into different perspectives based on the identification of the root of women’s oppression. Liberal feminists identified unequal access to existing economic and political systems, whereas radical feminists named patriarchy, the control of women by men, as the key oppressive system. Marxist and socialist feminists, following the writings of Karl Marx and Frederick Engels, believed that capitalism was the main determinant of women’s oppression. Socialist feminists engaged in active debates on the relationship between class and gender oppression, some arguing that women constituted a sexual class that functioned within the capitalist framework. Others, such as Betsy Hartmann, posited a dual-systems theory or a capitalist patriarchy in which patriarchy was viewed as a system of oppression anchored in material conditions (e.g., the institution of marriage, property ownership) acting alongside the relations of class. Issues of race and sexuality were largely absent from these debates.

Although second-wave feminists challenged traditional scholarship for positioning the experiences of men as universal, black feminists and lesbians critiqued these feminists for excluding issues of race and sexuality from feminist analysis, thus falsely universalizing the experiences of middle-class heterosexual white women. In the late 1970s only a few authors, mostly women of color, were writing about gender, race, and class as interconnected systems of oppression. The Combahee River Collective, a group of black feminist activists from Boston, is widely credited for first theorizing the interconnections between gender, race, class, and sexuality. In “A Black Feminist Statement” (1983) they outline how they view gender, race, class, and sexuality as connected: “We are actively committed to struggling against racial, sexual, and class oppression, and see as our particular task the development of integrated analysis and practice based upon the fact that the major systems of oppression are interlocking. The synthesis of these oppressions creates the conditions of our lives” (p. 210). An intersectional approach complicates analyses of power relations that give priority to one element of identity.

Although intersectionality theory emerged in the 1970s, its roots can be traced back to a speech delivered by Sojourner Truth (c. 1797–1883), a black woman who had been a slave, at the 1851 Women’s Rights Conference in Akron, Ohio. In this passage, she articulates how her identity is shaped not only by her gender, but also by her race and class: “That man over there says that women...”

Jonathan H. Marks

need to be helped into carriages, and lifted over ditches, and to have the best place everywhere. Nobody ever helps me into carriages, or over mud puddles, or gives me any best place. And ain’t I a woman?” (Painter 1996, p. 165).

According to Avtar Brah and Ann Phoenix (2004), “Sojourner Truth’s identity claims are thus relational, constructed in relation to white women and all men and clearly demonstrate that what we call ‘identities’ are not objects but processes constituted in and through power relations” (p. 77).

In the early twenty-first century, intersectionality theory received wide support from social science researchers. Many researchers adopted intersectionality theory in their development of research questions, methodologies, and analysis. Some researchers who used this approach framed the intersections of gender, race, and class so that a black woman would be seen as facing a “double jeopardy” due to the combined impact of gender and racial inequality. Elizabeth Spelman (1988) argued that treating interlocking systems of oppression as additive implies that processes of gender, race, and class are separate entities, and it ignores how these factors interact to shape lived experience. Intersectionality approaches the concepts of gender, race, and class as social constructions that vary across geography and time; markers of difference are not viewed as static traits, but as processes that are (re)produced in the daily actions of people.

Both qualitative and quantitative researchers have taken up intersectionality theory in their investigations into the workings of social reality, although qualitative approaches have far outnumbered quantitative studies. Marlene Kim (2002) applied an intersectionality framework to her quantitative investigation of how gender and race processes affect the wages of women in the United States. Her research indicates that black women face a “race penalty” in that when all factors are considered, they earn 7 percent less than white women in the same industries. Feminist economists Rose M. Brewer, Cecelia A. Conrad, and Mary C. King (2002) point out that there are many challenges of applying an intersectionality framework to the empirical investigation of social differentiation: “Even as we increasingly understand the mutually constitutive nature of color, caste, race, gender, and class, analytically, as categories of analysis and identity, the project remains difficult” (p. 5). Quantitative research studies tend to address issues of gender independent of race or class.

An important quantitative research project was conducted by Leslie McCall (2001), who analyzes the impact of gender, race, and class on wage inequality in four U.S. cities with different local economic contexts: Detroit, Miami, St. Louis, and Dallas. By combining an analysis of case-study and large-scale survey data, McCall demonstrates that gender and racial inequality have different consequences in different contexts; in some instances, a decrease in gender inequality is accompanied by an increase in racial inequality between women. She identifies configurations of inequality as a term to describe the shifting interactions between gender, race, and class. These configurations “reveal that in no local economy are all types of wage inequality systematically and simultaneously lower or higher; complex interactions of various dimensions of inequality are the norm” (p. 6). Her analysis is an important development in understanding the relationship between relations of gender, race, and class.

Researchers who use intersectionality theory present a more sophisticated, nuanced understanding of the workings of power relations. Susan Stanford Friedman (1995) proposed a framework of “relational positionality” that acknowledges how “the flow of power in multiple systems of domination is not always unidirectional. Victims can also be victimizers; agents of change can also be complicit, depending on the particular axis of power one considers” (p. 18). Sherene Razack (1998) argues that “it is vitally important to explore in a historical and site-specific way the meaning of race, economic status, class, disability, sexuality, and gender as they come together to structure women in different and shifting positions of power and privilege” (p. 12). The research of intersectionality theorists makes an important contribution to the social sciences; it is now considered incomplete scholarship in women’s studies or cultural studies for a researcher to undertake an analysis of gender relations without consideration of how race and class relations are also implicated.

INTERSUBJECTIVITY

In its most general sense of that which occurs between or exists among conscious human actors, intersubjectivity is little more than a synonym for “the social.” As used by social scientists, however, intersubjectivity usually denotes some set of relations, meanings, structures, practices, experiences, or phenomena evident in human life that cannot be reduced to or comprehended entirely in terms of either subjectivity (concerning psychological states of individual actors) or objectivity (concerning brute empirical facts about the objective world). In this sense, the concept is usually intended to overcome an unproductive oscillation between methodological subjectivism and objectivism. The concept is especially predominant in social theories and theories of the self.

Although German idealist philosophers Johann Fichte (1762–1814) and G. W. F. Hegel (1770–1831) stressed the importance of intersubjectivity, the concept became influential in the twentieth century through the work of American social psychologist George Herbert Mead (1863–1931). Mead claimed that the development of cognitive, moral, and emotional capacities in human individuals is only possible to the extent that they take part in symbolically mediated interactions with other persons. For Mead, then, ontogenesis is essentially and irreducibly intersubjective. He also put forward a social theory explaining how social norms, shared meanings, and systems of morality arise from and concretize the general structures of reciprocal perspective-taking required for symbolic interaction. In short, he argued that intersubjectivity—understood specifically in terms of linguistically mediated, reflexively grasped social action—furnishes the key to understanding mind, self, and society.

Although the work of Martin Heidegger (1899–1976) and Ludwig Wittgenstein (1889–1951) was often more directly inspirational, Mead’s bold claim that self and society are irreducibly intersubjective has been rearticulated and supported by many distinct subsequent inter-subjectivist approaches. Action theory, symbolic interactionism, lifeworld phenomenology, hermeneutic analysis, conversational analysis, ethnomethodology, social constructivism, dialogism, discourse theory, recognition theory, and objects relations theory all take intersubjectivity as central and irreducible. For example, Erving Goffman (1922–1982) insisted that we need a microanalysis of face-to-face interactions in order to properly understand the interpersonal interpretation, negotiation, and improvisation that constitute a society’s interaction order. While macro- and mesostructural phenomena may be important in setting the basic terms of interaction, social order according to Goffman is inexplicable without central reference to agents’ interpretations and strategies in actively developing their own action performances in everyday, interpersonal contexts. Harold Garfinkel and other ethnomethodologists likewise insist that social order is only possible because of the strongly normative character of a society’s particular everyday interaction patterns and norms.

Widely diverse social theorists influenced by phenomenology also center their analyses in intersubjective phenomena and structures. Most prominently, Alfred Schutz (1899–1959) sought to show how the lifeworld of persons—the mostly taken-for-granted knowledge, know-how, competences, norms, and behavioral patterns that are shared throughout a society—delimits and makes possible individual action and interaction. In particular, he sought to analyze the way in which the constitutive structures of any lifeworld shape social meanings and personal experiences, by attending to the lifeworld’s spatiotemporal, intentional, semantic, and role typifying and systematizing dimensions. Other theories analyze different aspects of the lifeworld: how experience and knowledge is embodied (Maurice Merleau-Ponty), the intersubjective construction of both social and natural reality (Peter Berger and Thomas Luckmann), the social construction of mind and mental concepts (Jeff Coulter), and the social power and inequalities involved in symbolic capital (Pierre Bourdieu). Finally, Jürgen Habermas emphasizes the linguistic basis of the lifeworld, constructing a theory of society in terms of the variety of types of communicative interaction, the pragmatic presuppositions of using language in order to achieve shared understandings and
action coordinations with others, and the role of communicative interaction for integrating society. While acknowledging that some types of social integration function independently of communicative action—paradigmatically economic and bureaucratic systems—Habermas claims that intersubjective communication is fundamental in, and irreplaceable for, human social life.

Diverse prominent theories of the self are united in supporting Mead’s claim that the self is developed and structured intersubjectively. Martin Buber’s (1878–1965) distinction between the different interpersonal attitudes involved in the I-Thou stance and the I-It stance leads to the insight that the development and maintenance of an integral sense of personal identity is fundamentally bound up with the capacity to interact with others from a performative attitude, rather than an objectivating one. Mead’s claim is also developed in diverse theories of the self: Habermas’s account of interactive competence and rational accountability, Axel Honneth’s and Charles Taylor’s theories of interpersonal recognition and identity development, Daniel Stern’s elucidation of the interpersonal world of infants, and psychoanalytic object-relations theories stressing the dependence of the ego on affective interpersonal bonds between self and significant others.

INTERVENTIONS, SOCIAL POLICY

Social policy interventions include policies affecting the social conditions under which people live. Social policy aims to improve human welfare and to meet human needs. Many policies that are ostensibly economic, such as cash assistance to the poor, fall under the rubric of social policy interventions because they have a direct impact on the social conditions under which people live and are aimed at improving human welfare and meeting human needs. Social policies may also regulate and govern human behavior in such areas as sexuality and morality. Policies that involve access to abortion or laws governing marriage and divorce therefore fall within the sphere of social policy interventions.

Between the 1880s and the 1920s, many European countries instituted pension and social insurance programs for industrial workers and needy individuals. These
programs became comprehensive social welfare systems in the 1950s to 1960s. Early U.S. social policy involved the most inclusive system of public education in the industrializing world, as well as generous benefits to elderly veterans and their families. The United States also instituted social benefits for women and their children. The Social Security Act of 1935 created a basic framework for U.S. social policy interventions that is still in place today. In the 1960s, in conjunction with the war on poverty, major new programs of public assistance were established in the United States.

Among comparably developed countries, the United States has the highest level of economic inequality and the lowest level of cash assistance to the poor. With noncash assistance added, the United States falls in the middle. Cash benefits require trust that recipients will spend the extra income on expenditures the public deems worthy. Noncash public assistance programs pay directly for those expenditures deemed worthy, such as food in the case of the Food Stamp Program or health care in the case of Medicaid.

EXAMPLES OF SOCIAL POLICY INTERVENTIONS

A broad set of public assistance or antipoverty programs exists in the United States; these programs constitute a fundamental social policy intervention. The four largest components of U.S. public assistance include: the Food Stamp Program; Medicaid; Aid to Families with Dependent Children (AFDC), replaced in 1996 with the Temporary Assistance to Needy Families (TANF) block grant; and the Earned Income Tax Credit (EITC).

The Food Stamp Program is a nationally provided program. It is the only public assistance program available to all poor people, whether or not they have children. The Food Stamp Program is the first line of defense against hunger in the United States. Food stamp recipients spend their benefits to buy eligible food in authorized retail stores. As family income increases, food stamp benefits decline. Therefore, recipients who live in states that provide less in the way of cash assistance to the poor receive more in food stamps.

Medicaid, established in 1965, pays for health-care costs among eligible low-income groups. The program is run by the states, with certain mandates from the federal government. Like all health-care costs, Medicaid costs have substantially increased over the 1980s, 1990s, and early 2000s. This is mostly due to increased costs for long-term care among the elderly and disabled, as well as the fact that the benefits expanded in the 1980s to include all poor children. Medicaid is the most costly of U.S. public assistance programs.

Aid to Families with Dependent Children (AFDC), commonly known as welfare, provides cash assistance to poor families with children. An individual receives the highest level of assistance from AFDC when she or he has the least income; in fact, for every extra dollar in income the recipient earns, a dollar is lost in benefits. In many cases, the economic reality of AFDC recipients’ lives means that neither welfare nor low-wage work gives them enough income to meet their families’ expenses. Moreover, inflation has steadily eroded the real value of AFDC benefits over the years. AFDC is a controversial social policy intervention, primarily due to changing views regarding the primary recipient population—single mothers. In 1996 Congress passed the Personal Responsibility and Work Opportunity Reconciliation Act, which implemented fundamental changes in the design and funding of public assistance programs in the United States, particularly AFDC. AFDC was abolished and replaced with a program called Temporary Assistance to Needy Families. States were expected to replace their AFDC programs with new programs of their own; federal mandates include work requirements for recipients and limited time periods for benefits.

The federal Earned Income Tax Credit (EITC) is another large and growing public assistance program. EITC is a refundable tax credit that reduces or eliminates the taxes that low-income working people pay. The program frequently operates as a wage subsidy for low-income workers. People who work, earn low wages, and have children are eligible to receive EITC. In contrast to AFDC, since EITC pays nothing for people who are not working, it provides an incentive to work, assuming that recipients understand how EITC operates. The rationale underlying this intervention is that employment alone is insufficient to bring people out of poverty. By the early 2000s, EITC had become one of the largest antipoverty tools in the United States.

Another example of an important, albeit controversial, social policy intervention is affirmative action. Affirmative action is a policy or program whose stated goal is to redress past or present discrimination through active measures to ensure equal opportunity; generally to higher education and employment. The stated goal of affirmative action is to counteract discrimination sufficiently such that the power elite reflect the demographics of society at large, at which point such a strategy will no longer be necessary. Groups who are targeted for affirmative action are characterized by race, gender, ethnicity, or disability status.

Proponents of affirmative action generally advocate it either as a means to address past discrimination or to enhance racial, ethnic, gender, or other diversity. Proponents argue that the simple adoption of meritocratic
principles of race blindness or gender blindness will not suffice to change the situation for several reasons: (1) Discriminatory practices of the past preclude the acquisition of “merit” by limiting access to educational opportunities and job experiences; (2) ostensible measures of “merit” may be biased toward the same groups who are already empowered; and (3) regardless of overt principles, people already in positions of power are likely to hire people they already know or people from similar backgrounds. Opponents claim that affirmative action: (1) acts as a new form of discrimination and benefits privileged individuals within minority racial groups (such as middle- to upper-class blacks) at the expense of disenfranchised individuals within majority racial groups (such as poor whites); (2) increases racial tension and creates a stigma such that all minority groups within a college or employment setting are perceived as having received special treatment; and (3) creates a skill “mismatch” (i.e., individuals who are less qualified than their peers are admitted into more rigorous programs in which they cannot adequately perform).

EVALUATION OF THE EFFECTS OF SOCIAL POLICY INTERVENTIONS

A central issue in the evaluation of social policy interventions is how the outcome of interest is defined. Many Americans contend that because high poverty rates continue to exist in the United States, antipoverty programs must be ineffective. However, many public assistance programs have accomplished exactly what they were intended to accomplish. Most of the antipoverty programs were not designed to eliminate poverty, but to provide assistance to needy families. For example, the Food Stamp Program has improved nutrition among the poor, and Medicaid has increased access to medical care and contributed to improvements in the health of the poor. The combined impact of these programs has also improved the health of pregnant women and reduced low birth weights among infants born to low-income mothers.

Studies have found that while cash assistance for the poor does not do much to decrease the overall poverty rate in the United States, such assistance provides more cash income to families than they would have otherwise, making them less poor. In the absence of welfare benefits, individuals work more on average, but do not earn as much money as they would receive or did receive from welfare. Moreover, earnings of less-educated U.S. workers have stagnated or fallen since about the 1970s, such that employment is not necessarily effective in combating poverty.

Affirmative action is another example of a controversial social policy that provokes intense debate regarding its effects. The evidence suggests that affirmative action has had a major impact on the representation of minorities in university admissions and employment, even if the overall numbers of redistributed positions is small. Replacement of affirmative action programs based on race and gender with class-based practices is likely to reduce the presence of minorities on college campuses while doing little to improve the overall position of white males. There is some evidence that the performance of students admitted to colleges and universities with the aid of affirmative action lags behind that of students admitted without such aid. However, there may be an overall benefit to more diversity on campuses. Moreover, minority students benefit greatly in the labor market from having attended college. Nevertheless, affirmative action programs remain under intense challenge.

Serious evaluation of any social policy intervention requires some sort of comparison group. A comparison group provides a means of evaluating the counterfactual, that is, what would have happened to program recipients in the absence of participation in the program. A randomized experiment where one group is assigned to receive the benefits of a program while another group receives no such benefits is typically considered the best way to deduce causation. However, most programs, particularly nationwide entitlement programs, provide limited opportunities for randomized experiments.

INTERVENTIONS, SOCIAL SKILLS

Social relationships among individuals account for much of what is studied in the social sciences. Considerable research supports the essential role of social relationships
in behavioral, emotional, and academic/vocational well-being, showing that relationships with others directly impact self-esteem, daily functioning, and life success. Positive relationships foster positive well-being while problematic relationships result in poorer functioning. In keeping with these findings, the goal of social skills interventions (SSI) is to train individuals in specific skills and strategies that foster positive relationships.

One of the first theorists to propose that social relations with peers have a lasting impact on future intimate relationships as well as on personality development was Harry Stack Sullivan. In his seminal book *The Interpersonal Theory of Psychiatry* (1953), Sullivan postulated that childhood friendships, or “chumships,” play a causal role in children’s understanding of social roles and social rules. This belief system then determines interpersonal actions and reactions throughout adolescence and adulthood. Correspondingly, though SSI have been applied across the life span, they are most frequently practiced and studied with children during the elementary school years.

Generally, learning theory is the theoretical basis of SSI through which individuals are taught specific social skills and given opportunities to practice in a structured fashion. The assumption in SSI work is that factors within the individual are largely responsible for the quality of one’s social relationships; if those factors are changed, then changes in social relationships will follow. Thus, the focus of SSI is on the individual, rather than the environment or other external contributing factors. However, conducting SSI within a group setting is considered an important ingredient for effecting change. In a group, individuals are able to learn and practice skills within a social context of same-aged peers. However, the group setting is more structured and safe than real-life peer settings, so fear of rejection and teasing is decreased and willingness to try new social behaviors is increased and supported. The social interactions within the group are also observed by group leaders who can then intervene when problems emerge and reinforce positive changes as they occur. The group leader serves as a coach, providing constructive criticism, alternative suggestions, and positive reinforcement.

Behavioral skills have traditionally been the mainstay of SSI. How to control impulses, how to cooperate with others, and how to initiate contact with others are basic behavioral skills taught through most SSI. In the 1980s, social scientists began to recognize the mutual impact of thought, emotion, and behavior, and increasingly incorporated cognitive and emotional skills into SSI. Cognitive skill training focuses on helping individuals identify, challenge, and restructure maladaptive thought patterns. Negative social experiences, such as being bullied, tend to engender negative expectations for future social encounters. Testing negative assumptions and managing their influence on behavior is a core social-cognitive skill taught through SSI. Emotional skill training focuses on building self-awareness of how one feels in the moment and learning to manage those emotions. SSI help individuals recognize when emotions, such as anger or hurt, are short-circuiting social skills so they can control those emotions before acting.

SSI are appropriate for anyone who experiences social difficulties, such as isolation, rejection, or bullying. However, certain groups are at higher risk for social problems and, therefore, benefit particularly from SSI. Aggressive individuals experience high levels of conflict that are closely linked with negative relationships. Persons with attention deficit hyperactivity disorder (ADHD) exhibit increased activity level and impulsivity that are seen as intrusive and disruptive by peers. Individuals with developmental disorders, such as autism, or learning or physical disabilities stand out as different from peers and are more likely to display immature, awkward social behaviors that foster peer victimization and rejection. Finally, persons with emotional difficulties, such as depression or anxiety, are likely to withdraw from social interactions and experience isolation.

Research on SSI is intended to establish the effectiveness of intervention and better understand the mechanisms of change. A large literature exists evaluating the efficacy of different SSI with different populations and ages. A thorough review of interventions with school-age children was conducted by Mark Greenberg and colleagues in 2001. Overall, support for SSI for improving social competence and relationships has been found, although effect sizes tend to be moderate. SSI are most effective when: (1) cognitive and emotional skill training are included rather than behavioral skills alone; (2) training occurs over a longer period; (3) multiple components are used to bridge home, school, and clinical settings; and (4) training emphasizes both strengths and weaknesses of the individual.

**BIBLIOGRAPHY**

The interwar years (1919–1938) pose a challenging puzzle for students of globalization: Why did the prolonged period of relative peace and prosperity in Europe, from 1815 to 1914, give way to world war, economic collapse, and the rise of fascism and socialism?

The interwar period began with the Paris Peace Conference and the Treaty of Versailles, which formally ended World War I—the "Great War"—in 1919. The war destroyed the Westphalian System under which elites of government colluded to channel the fate of Europe's empires and colonial subjects. The Treaty of Versailles humiliated Germany and imposed burdensome reparation payments. The war also saddled with national debts the other defeated Central Powers (Austria-Hungary and the Ottoman Empire) and the victorious Allies (France, Russia, Britain, Italy, and the United States).

This period witnessed efforts to construct a self-regulating global market, the rise of the human rights framework, and the emergence of new international political bodies, all of which ultimately failed, but which left lasting impacts on the economic, social, and political landscape of the twentieth century. Internationalists, who rejected policies of economic and political isolationism, pursued global peace through two mechanisms: the creation of the League of Nations and the restoration of the gold standard.

With the Westphalian balance of power in ruins, the U.S. president Woodrow Wilson promoted the League of Nations as the primary body for a new style of international relations. However, the League of Nations, which first met in November 1920, initially represented only forty-two nations. Germany, Russia, and the United States were notably absent. Embarrassingly for Wilson, the United States voted in 1919 against membership in the League, and the United States never joined. Although it refused to participate in international political bodies such as the League, the United States remained involved in the economic affairs of Europe. Throughout the 1920s the United States insisted upon repayment of the loans made to Britain and France during the war. France and Britain in turn insisted that Germany repay to them the enormous reparations agreed to at Versailles. But the strain on the German economy threatened to disrupt the German political and economic order and weaken European stability in general. The Dawes Plan in 1924 and the Young Plan in 1929 both refinanced international loans to Germany. But toward the end of 1929, the New York stock market boom had absorbed all available funds for foreign investment, which placed severe pressure on a German economy that had become dependent on this flow.

Other internationalists promoted a return to the gold standard. Conventional wisdom held that banknotes had value only if they represented gold. Between the 1870s and until the start of World War I, a transnational network of elites embracing market liberalism created a financial mechanism called the gold standard to extend the scope of markets internationally by enabling people in different countries with different currencies to freely engage in transactions with each other. The idea was to create a mechanism for global self-regulation by imposing a gold standard that relied on three rules: First, set the value of any nation's currency in relation to a fixed amount of gold and commit to buying and selling gold at that price; second, base the domestic money supply on the quantity of gold that your nation is holding in its reserves, so that circulating currency will be backed by gold; and third, give residents maximum freedom to engage in international economic transactions. However, efforts to restore the gold standard and an open world economy after World War I failed to reestablish the stability of the prewar period. The openness of the international economy only served to transmit deflationary pressures from one country to another after 1929, and acted as an obstacle to national recovery programs in the early 1930s.

In the United States, the Federal Reserve Board refused to manage the economy according to the gold standard. It instead acted to neutralize the expansionary effects of large gold imports into the United States from Europe, preventing a domestic price rise while placing an even greater burden of adjustment on European economies already facing severe economic problems. Despite the United States' contributions to the structural weakness of the interwar gold standard, it was not until the Great Depression that internationalists abandoned their experiment with restoring the gold standard. Germany, under the Nazis, built up a structure of exchange controls to close their economy off from the rest of the world, and U.S. president Franklin D. Roosevelt began institutionalizing his more protectionist New Deal policies.

More enduring signs of cultural transnationalism during this period were expressed in the form of jazz music, which was popularized initially in rapidly urbanizing North America but soon traveled to, and became localized within, Paris, as well as to more distant places such as Japan and China. Indeed, the interwar years are frequently referred to as "the Jazz Age," and the music became an important symbol of an emerging aesthetic of modernism, and cultural modernity more generally.

Despite earnest international efforts to construct institutions to secure global peace, and some signs of cultural transnationalism, conflict within nations was widespread and laid the groundwork for another descent into total war. In 1917 the Bolsheviks established a single-party dictatorship under the leadership of Vladimir Lenin.
after seizing power in the Russian Revolution. After Lenin's death in 1924, Joseph Stalin abandoned Lenin's economic policy for a totalitarian system of central planning. When the better-off peasants (kulaks) rebelled in 1929 to 1930, Stalin initiated a reign of terror that killed three million people.

In the United States rapid demobilization and the lack of price controls sparked inflation and unemployment, which intensified competition for jobs among the working class. In 1919 more than twenty race riots erupted in cities across the country. White workers violently protested returning black soldiers' demand for equal rights to employment. Americans watched their stock market roar in the 1920s, only to suffer the Great Depression in the 1930s.

In China the Manchu Dynasty fell in 1911, leaving local warlords to tax their populations. In the 1920s Mao Zedong cofounded the Chinese Communist Party, and the nationalist organization Guomindang (GMD) became a mass party under the leadership of Chiang Kai-shek. By 1931 the GMD had defeated most of the warlords, confined the Communists to one rural region in the south, and gained nominal control of most of the country. Chinese peasants, hard hit by the Great Depression, helped Mao launch a comeback. Chiang was forced to contend with this Communist threat at the same time that he was battling Japanese encroachments on, and (in 1937) invasion of, Chinese territory.

Nationalism also grew in the Middle East during the collapse of the Ottoman Empire. During World War I the British had heavily sponsored Arab nationalist thought and ideology to challenge the Ottoman Empire. However, Britain's secret Sykes-Picot Agreement with France divided the eastern Arab lands between the two imperial powers, and Arab nationalism became the basis for an important anticolonial movement.

In Italy political tensions between fascist “black shirts” and Communist “red shirts” brought the country to the brink of civil war. The fascist leader Benito Mussolini took power, later became one of Hitler's most important allies, and provided support for the fascist cause, fueling Spain's civil war. In 1936 Spanish military nationalists under General Francisco Franco's leadership declared their intention to overthrow the government that replaced the monarchy. The stage was now set for World War II (1939–1945).

The intifada represented both a departure from as well as a reproduction of prior forms of Palestinian resistance against the Israeli occupation since 1967. The Palestinian repertoire of resistance up to 1987 had consisted of sporadic cycles of spontaneous demonstrations, strikes, and sit-ins, usually violently suppressed by the Israeli military and often resulting in Palestinian deaths. Those deaths were mourned in elaborate, mass-attended funerals that often ended in street protests, which were met by further Israeli military punishments, including the closing of universities, the bulldozing of Palestinian homes and olive trees, and the detention without trials and deportation of the activists. The difference with the intifada was that although it was initially spontaneous, it quickly became an organized and sustained popular resistance with a clear agenda of ending the Israeli occupation and demanding Palestinian self-determination. A broad strategy was articulated by its local leaders, the Unified National Leadership of the Uprising (UNLU), an underground umbrella coalition of the main Palestinian political factions in the occupied territories. The UNLU periodically published leaflets to inform the public and coordinate resistance activities in various parts of the territories; the Palestine Liberation Organization (PLO), stationed in Tunis, lent its support. Posing as an alternative to the UNLU, the Muslim Brotherhood mobilized a militant wing, Hamas, and joined the uprising, issuing its own leaflets that incorporated an Islamic ideology into the struggle.

The main aim of the uprising was to denormalize life under the Israeli occupation while increasing the cost of the occupation on Israel by using civil disobedience and protests. The UNLU leaflets urged Palestinians to strikes and peaceful protests (armed struggle by the civilian Palestinian population under occupation was rejected, and when it occurred, was limited); to stop paying taxes (which led to the tax rebellion in the town of Beit Sahour in the West Bank); and to boycott Israeli products, work in Israel, and all posts connected to Israeli administration of the territories.

The uprising was a decentralized movement involving coordination between the underground leadership and the “people’s committees” that sprang up in the refugee camps and the villages of the territories and organized local initiatives. The mass-based structure of the uprising was possible only because people’s committees had already been in place since the 1970s as part of Palestinian institution building to counteract the deteriorating conditions under occupation. When Palestinians realized in the 1970s that a speedy reversal of the occupation was not in sight, they focused on surviving on their occupied land, awaiting liberation from the external Palestinian national movement, and applied the term steadfastness to the process. In the absence of municipalities, they mobilized volunteer work committees, including medical relief committees that provided preventive medical care to the camps and villages and women’s work committees that offered income-generating projects and support for prisoners’ families. These and other groups formed the basis for sustaining the uprising and its goal of delinking from the occupation by meeting civil needs, from health to agriculture.

The Israeli response was repression, curfews, labor control through border control, and general movement restrictions. The repressive and often violent tactics supported by the Israeli defense minister Yitzhak Rabin (1922–1995) in January 1988 translated into high Palestinian casualties and detention rates. Between 1988 and 1990, one in twenty-two Palestinian children was either killed or injured, according to the Israeli human rights organization B’Tselem. By the time of the signing of the Oslo Accords in September 1993 between the PLO and Israel, the intifada had already waned, and casualties topped 1,500.

The uprising made visible the Palestinians as a people struggling against Israeli occupation through the images of the stone throwers—previously their plight had been coded under the “Arab-Israeli conflict”—and made it difficult for Israel to continue the occupation as before. Moreover, the uprising realized Palestinian will to be represented solely by the PLO (Jordan halted its administrative responsibility for the West Bank in July 1988). The Palestine National Council session in Algiers in November 1988 issued a Declaration of Independence of Palestine, making Jerusalem its capital. Shortly afterward, Yasser Arafat (1929–2004) promised future, formal recognition of Israel and Palestine’s readiness for territorial concessions in the United Nations General Assembly address in December 1988.

Although Palestinians greeted the arrival of the Palestinian Authority in Gaza in 1994 as a symbol of the triumph of their intifada, their hopes for an independent state were not realized. Israel retained military and economic controls over Gaza’s borders, air and sea routes, international relations, and overall security even after its disengagement, and more than half of the West Bank remained under Israeli control in 2000, with additional areas under Israeli security control. Palestinian living standards continued to deteriorate, falling to pre-intifada levels, as the Israeli policy of border closure since March 1993 placed Gazans in a prison-like situation with limited work options, mostly in the inflated Palestinian security forces.

A second widespread uprising broke out in reaction to events on September 28, 2000, when the controversial Israeli politician Ariel Sharon (b. 1928) made a provocative visit to Al-Aqsa mosque in East Jerusalem, deploying thousands of security forces to seal off the area. The uprising of December 9, 1987, came to be referred to as...
the “first intifada” and the September 28, 2000, uprising came to be referred to as the “second intifada,” or the “Al-Aqsa intifada.”

By 2000 the Palestinian Authority was present in parts of the territories and more of the Palestinian population was armed, so during the second intifada there was greater focus on armed struggle and greater use of full military force by Israel, which constructs the intifada as a war between states. The Palestinian Authority is caught in a double bind: Israel expects them to contain the armed struggle, but at the same time they must maintain legitimacy among Palestinians, and this perpetuates not only the uprising but also internal Palestinian confrontation, with increased hardships for daily life for Palestinians.

INUIT
The Inuit make their homes in Chukotka, Alaska, Arctic Canada and Labrador, and Greenland, and are one of the several indigenous peoples of the Circumpolar North. The name Inuit (singular, Inuk) has political as well as cultural and linguistic connotations. It means “the people” in Inuktitut, the language of the Inuit in Greenland and the central and eastern Canadian Arctic. Since the late 1970s the term has become the political designation for all of the peoples once known as Eskimos. The term Eskimo remains correct for archaeologically known populations.

Numbering approximately 150,000 people in 2006, contemporary Inuit are diverse in lifestyle, cultural practices, language, and economic and social circumstances. Within the broad political category Inuit, there are four major cultural divisions: Siberian Yupik, Alutiiq, Alaskan Yup’ik, and Inuit. Those who call themselves Inuit make additional regional, language, and cultural distinctions such that those in north Alaska are known as Inupiat, while Inuit in Canada differentiate among Inuvialuit, Inuinnaqtu, and Inuit. Greenlanders sometimes refer to themselves as Inuit, but also use the regional and cultural designations of Kalaallit, Inughuit, and It. While these contemporary distinctions have some basis in cultural, linguistic, and regional difference, the current divisions are also a result of colonial and administrative histories that reified some differences and denied others.

CULTURAL ORIGINS
Linguistic, cultural, and archaeological data indicate that the Inuit populations are related to the indigenous peoples of Siberia, and Inuit cultures most likely have their origins in Siberia or Central Asia. Archaeological evidence suggests that the ancestors of contemporary Inuit peoples moved across the Bering Strait in several waves, and probably in small groups, as early as 5000 B.C.E. These hunting peoples spread out across the North American Arctic, where they depended on both land and marine animals. Around 1,500 years ago, the maritime-adapted peoples in southwest Alaska began spreading north, establishing themselves as whale hunters in north Alaska. Contemporary Inupiat are their descendants. Some of these northern Alaskans moved eastward into the Arctic Archipelago and Greenland during a warming period around 800 to 1000 C.E., and are the ancestors of the contemporary Inuit of Canada and Greenland. The Thule Eskimos, as they are known, either replaced or absorbed the Eskimo cultures that had preceded them.

There are similarities as well as differences between the various Inuit peoples. The similarities, which are most striking in terms of language and traditional cosmological beliefs, are clearly due to the relatively recent geographic divergence between groups. Linguists distinguish at least two closely related languages, Inuktitut and Yupiaq, each with several distinct but mutually intelligible dialects. Inuit cosmology attributed a life force to all aspects of the natu-
Humans, in order to survive and prosper, attended to numerous taboos and engaged in morally correct behavior. Animals were said to give themselves to those hunters who were respectful, modest, and generous. Souls of the dead, both human and animal, returned to the world of the living in new bodies. Alaskan Yupiit (plural of Yup’ik), for example, celebrated a Bladder Festival each winter in which the souls of the sea mammals killed that year were feasted and then returned to the sea where they would be reborn. The recycling of souls is also reflected in human naming practices, which bestow the name, and thus the soul, of a recently deceased person upon a newborn infant. This tradition of naming children continues, and many contemporary Inuit contend that the name/soul chooses the child rather than being chosen for the child.

The differences between the various Inuit peoples, in contrast, are superficial and generally reflect differences in material circumstances rather than distinctions in life ways and social values. Many of the differences result from variation in the natural environment across Inuit lands, which encompass a number of ecosystems and climatic conditions. At the southern margin, Alutiiq (plural of Alutiq) and Yupiit lived in subarctic boreal forest zones, built sod houses in permanent winter villages, and had economic security provided by dependable stocks of fish and sea mammals. Farther north, Inupiat reliance on bowhead whales enabled them to establish semipermanent villages of up to five hundred people. Large numbers of people living together and cooperating in subsistence whaling demanded a fairly formal political organization. Inupiat were led by male umialik (singular, umialik; literally, “boat owners”) and their wives, who organized and directed whale hunting activities and later distributed the proceeds of the hunt. The lit, who live along the narrow rocky coastline of eastern Greenland, in contrast, led a precarious existence and occupied multifamily longhouses of stone and sod.

Only Inuit in the central and eastern Canadian Arctic lived in domed snowhouses and hunted seals at breathing holes. This stereotype of Inuit life was true for them only during midwinter and early spring. They and Inuit elsewhere depended upon seasonally variable marine and terrestrial animals for food, clothing, and tools. All Inuit peoples in the various regions and ecosystems adapted their communities and developed sophisticated technologies in order to survive and prosper.

COLONIAL EXPERIENCES

Inuit in Greenland, and possibly those in Labrador and on Baffin Island, had some contacts with the Norse colonists in the tenth century. In 1576 English explorer Martin Frobisher (c. 1535–1594) encountered Inuit at Baffin Island while searching for a northwest passage to Asia. His was the first of numerous, sometimes sustained European encounters with modern Inuit. It was only in the early eighteenth century that Europeans successfully colonized Inuit lands. The Danes, hoping to restore contact with the lost Norse, established a colony on the west coast of Greenland in 1721. A few years later Russians, having already established trading colonies in Chukotka, began exploring and settling Alutiiq regions of Alaska. Both established trading monopolies and sought to convert Inuit to Christianity and to make them into reliable suppliers of fur and other renewable resources.

Inuit in other parts of the Arctic, though not directly subjected to colonizing settlers, experienced the disruptive influence of whalers, traders, prospectors, and missionaries. The purchase by the United States of Alaska from Russia in 1867 and Canada’s acquisition of British Arctic territories in 1870 and 1880 set the stage for those nations to administer Inuit lands and peoples. For the most part, however, both nations left the day-to-day administration to missionaries and traders. Inuit in both nations received the education, health care, and other public services provided to citizens of modern nation-states only after World War II (1939–1945).

Since the 1950s there have been dramatic changes in the social and material life of Inuit in all four nations. Some of the changes resulting from economic modernization and government administration have had positive consequences. Still, Inuit in all four nations have also suffered forced relocations, the imposition of alien cultural values and economic systems, and the reorganization of domestic and community life.

CONTEMPORARY CONCERNS

Today Inuit struggle to participate as citizens of modern nations while retaining a degree of cultural self-determination. There are concerns regarding resource development, economic and food security, education, language retention, health, and climate change. Greenlanders have succeeded in institutionalizing their language as the everyday vernacular of work and government, while the Siberian Yupik language is nearly extinct. The language situation in Alaska and Canada is mixed. Inuit have been required to adopt the political institutions and structures of their various nations. In all regions but Siberia, Inuit constitute a majority of the population in their traditional lands. Thus, they are able to maintain a measure of control over resource development, education, and other public services. This situation is recent. Struggles over resource development reached a climax in the 1970s and were catalysts for the settlement of aboriginal land claims in Alaska and Canada.

Hunting and the management of wildlife are also salient issues for contemporary Inuit. Although all Inuit
live in modern communities, and many work for wages, they have retained a cultural identification with hunting. Having access to and eating traditional foods continues to be socially, emotionally, and culturally valued. This traditional activity appears to be threatened by global climate change, which has created unstable, unpredictable, and dangerous weather conditions in the Arctic and threatens the survival of many animal species. The Inuit Circumpolar Conference, a nongovernmental organization representing Inuit in international affairs, has taken on climate change as its central focus and has argued that global climate change must be considered a human rights issue.

INVENTORIES

Inventories are sets of goods and materials held available to cover immediate or future needs. Inventories can be goods and materials for sale after some processing or as they are, or they can be goods (like fixtures, supplies, furniture, or equipment) that are not for sale but are nevertheless kept by organizations, manufacturers, and service providers.

In business, inventories are assets that are used in the productive process and transformed to realize sales of the final products the market demands. They may be classified in three major categories: raw materials, work in process, and finished goods.

Inventories of raw materials are the collections of items used to begin the production process of a firm. They could be materials from agricultural, forest, or mining operations, or they could be the finished goods of another company. For example, a computer microchip could be the final product of a firm that manufactures microchips and a raw material for a firm that manufactures personal computers. Work-in-process inventories exist and are created in all the stages of the production process from the moment raw materials are received to the stage just before the production of the final goods ready for sale. An inventory of final goods represents the last stage of the production process. It is a collection of items that are ready to be sold to customers, having been inspected for quality to meet certain standards.

Inventories are acquired based on a production schedule and a sales forecast to determine the target level of inventories in each category. If the inventory level is too high, the company faces an unnecessarily high cost of carrying inventories. If the level is too low, the firm might not have enough materials for its production process and risks losing sales and dissatisfying its clients by not meeting their demand. The management of a company must therefore determine how much inventory it should carry by evaluating the costs with the production requirements and customer demand.

COMPOSITION OF INVENTORIES

The composition of a firm’s inventories depends on several factors. Raw-materials inventories depend on the plans and schedules of production, the seasonality of sales, the available technology, the level of confidence toward the various suppliers for the on-time delivery of the needed goods, and several other factors. The level of work-in-process inventories depends on the type of the finished goods to be made ready for sale and the complexity of the production process. The level of finished-goods inventories depends on external factors, such as the expectations of the consumers and other market forces.

Inventories in business have certain financial characteristics that can be divided into three categories. First, they are part of the current assets on a firm’s balance sheet and in most cases can be converted into cash during a period of one year. (There is an exception in some specialized industries in which the conversion might take longer.) Second, they are the least liquid of the current assets. This means that in companies with high variability in sales and production processes, it is more difficult to liquidate the company’s inventories when needed unless they are sold at a discount, or less than their true value. Third, during the various inventory stages beginning with the purchase of raw-materials inventories until the realized sales of finished-goods inventories, there exist certain time lags that can have a positive or a negative effect for the firm. These are:

Manufacturing lag: The inventories that are bought by the company from its suppliers are usually raw materials. The payment for these inventories is usually made on credit. The credit period usually
is longer than one month, while other operating expenses of the firm, such as labor and wages, must be paid within a month. Furthermore, the firm can have the needed inventories available before it covers its obligations to its suppliers. Hence the firm has a type of financing for the goods it has obtained without any financial cost. This lag has a positive effect for the company.

Stockage lag: When the finished goods inventories are ready to be sold, in most cases they are not sold immediately and therefore do not create cash inflows. However, there are many cash outflows for the payment of labor, the payment of suppliers, and other expenses of the production process. This delay in selling the inventories and creating cash inflows to meet the realized cash outflows has a cost to the firm in reducing the firm's liquidity.

Sales lag: Even when sales are realized for the finished-goods inventories, they could be on credit and not cash sales, creating accounts receivable for the firm that sells the inventory. These accounts receivable could take up to a year to be paid and generate cash inflows. This type of cost is called the cost of maintaining or creating accounts receivable.

A company keeps inventories for the reasons of transaction, safety, and arbitrage. For the purpose of transactions, a firm keeps inventories of all types to have raw materials to work with and to have finished goods to sell in order to minimize or eliminate the risk of stock outs, (the risk of not having enough inventories of a certain type needed in the production process, so production will not stop or be delayed) or total depletion of inventory and to make financial transactions. If it keeps large amounts of inventories, the cost of investing in inventories rises, but the likelihood of stock outs falls. For the purpose of safety in meeting product demand, a firm must keep a high enough level of inventories to meet the demand for its products. For the purpose of arbitrage, a firm might keep a high level of inventories to take advantage of situations where prices are expected to increase. A firm that has bought or produced inventories at a low cost may profit by selling them later at higher prices. Furthermore, by purchasing higher amounts of raw materials, a firm can take advantage of possible discounts offered by its suppliers due to the larger quantities ordered.

**CATEGORIES OF COSTS**

A company might consider four major categories of costs before making significant decisions regarding inventories. The first category is carrying, or holding, costs. This category relates to the keeping of inventories and can be distinguished into the following specific types of carrying costs:

- **Storage and handling costs**: A firm needs to store its inventories in specific locations it owns or rents. This involves rental costs or the opportunity costs of using the storage areas rather than renting them to others along with the labor expenses of moving, storing, cleaning, distributing, reporting, securing, and generally handling the inventories.

- **DeSTRUCTION or theft costs**: Once a firm stores its inventories in specific locations, it needs to protect them from theft or destruction from those outside or inside the company.

- **Security costs**: Both the inventories and their storage locations have to be secured from fires, floods, accidents, and other natural catastrophes, usually through a purchased security or insurance program.

- **Age costs**: Certain categories of inventories, such as medicine, food, and computer products, have an expiration date beyond which they become obsolete and unfit for sale. The cost of keeping inventory beyond its expiration date is the age cost.

The second cost category is the ordering costs, which concern the placement of orders to the firm's suppliers. Each order that is received by a supplier has costs for the invoice to be issued and paid, for the transportation of the goods, for their quality inspection once the goods arrive, and so on. If a firm reduces the number of orders it places (making fewer but larger orders instead), it also reduces the total ordering costs of its inventories and becomes more profitable.

The third category is the opportunity costs, which are related to the amount of funds invested in inventories. If a large amount of funds is tied up in inventories, the firm loses opportunities it might have had to invest its finances instead in more profitable opportunities. Furthermore, if inventories are financed by borrowed funds, this carries interest costs that the firm has to pay back, thereby reducing its profitability.

The fourth category is the stock out costs or the costs associated with keeping too low an inventory or depleting an inventory. This can cause breaks and delays in the production of the finished goods, with negative consequences for the firm. It will have dissatisfied clients and customers, it might lose sales, it might have to pay fees for delaying its products' delivery, and it will damage its reputation.

According to Geoff Relph and Peter Barrar (2003), there
is also an opposite type of cost to stock out costs: that of having too much inventory, or overage. They suggest that firms should formally plan overage since an effective control of overage will enhance the company's profitability by minimizing the investment in inventories.

Certain factors affect the level of inventories a firm should carry to be profitable and efficient. These include:

- the required materials for each stage in the production process;
- the sales forecast;
- seasonal or cyclical factors that characterize the firm's sales during a year; and
- changes in technology that may render the finished-goods inventories obsolete.

**INVENTORY MANAGEMENT**

Inventory-management techniques aim to reduce the total inventory costs by holding and ordering inventories in the most efficient ways. They are covered extensively in special courses of production management. Inventory management also has economic consequences for a business and affects the value of the firm, so it is also studied from a financial point of view. The most common inventory management techniques follow.

The ABC system separates inventories into the categories A, B, and C according to their importance and nature so the total cost of inventory control can be reduced. The most valuable inventories are in category A, while the least important ones are category C.

The economic ordering quantity (EOQ) system uses a simple mathematical model to determine the ideal quantity of each order of inventories that will reduce the total ordering and carrying costs.

The system of reorder point is based on the EOQ model and shows the quantity of inventories that should be on hand when an order is placed to keep the total inventory costs at a minimum.

The automated system of inventory control is used by firms that have many products and determines the optimal quantities to be ordered based on the EOQ. It is a dynamic system that is easily adjusted depending on a company's needs.

The just-in-time inventory system is a system first introduced in Japan that minimizes the level of inventories a firm carries and the investment in them by achieving a perfect coordination between the ordering and receiving of necessary inventories at each stage of the production process. Hence no inventory stocks are created, and the inventory costs are kept at a minimum. The disadvantage of this system is that if the coordination is interrupted between the product suppliers and the customers' orders, the costs can be high.

**NATIONAL CYCLES**

Inventories also play an important role in national accounts. Some short-term macroeconomic fluctuations are attributed to the inventory cycle. Goods held as inventories are considered an investment and are counted for the year produced, not the year sold. Although inventories are a small portion of the overall investment sector, all the inventories from all the businesses in one economy constitute a critical component of the gross domestic product (GDP).

If the economy is moving toward a recession period, an undesired accumulation of inventories is a negative signal. Leading up to a recession, consumers have less liquidity and reduce their purchases. This leads to fewer sales of goods and services, which causes inventories of finished goods to increase. As inventories pile up, businesses reduce their production of goods to keep costs low. Since there is less productive activity, fewer employees are needed, and firms lay off staff to further reduce costs. Unemployment rises, output falls, GDP growth falls, and the economy goes into a recession. The idea that a recession might be caused by low product demand was introduced as early as 1889 by Albert Frederick Mummery and J. A. Hobson in their book *The Physiology of Industry* and upset the neoclassical economists. However, the British economist John Maynard Keynes (1936) praised Mummery and Hobson for their “heresy,” as Keynes called their proposition. Mummery and Hobson further proposed that too much saving has a negative effect in the economy since it leads to underconsumption. Lower levels of consumption will mean less demand for goods and services, which will cause the piling up of inventories in the immediate future and eventually will lead to lower production output, more unemployment, and a decrease of the GDP.

Conversely, an undesired or unexpected decrease in business inventories means that the demand for goods is greater than the one predicted by the firms, and the existing inventories become depleted quickly. Businesses reorder more inventories, hire more employees, and increase production to meet the increased demand and realize higher sales. As this phenomenon occurs throughout the economy, the unemployment rate falls, and the economic output rises, resulting in an increase in economic growth as measured by the GNP.

In addition, with more jobs, less unemployment, and higher output, income also increases and contributes further to a rise in the demand for goods and services. Higher
demand, though, leads to higher prices. The level of prices goes up, creating demand-pull inflation. As demand for more labor rises, wages increase, which will further increase the rate of inflation.

Inventories can thus be considered a leading indicator of business cycles. Changes in the variable of business inventories can lead to changes in the future condition of the economy and economic growth. Economic analysts therefore monitor the aggregate levels of business inventories for potential changes in future economic growth.

**INVERSE MATRIX**

The concept of inverse matrix is somewhat analogous to that of the reciprocal of a number. If $a$ is a nonzero number, then $1/a$ is its reciprocal. The fraction $1/a$ is often written as $a^{-1}$. Aside from the fact that only nonzero numbers have reciprocals, the key property of a nonzero number and its reciprocal is that their product is 1, that is, $a \cdot a^{-1} = 1$. This makes $a^{-1}$ the multiplicative inverse of the nonzero number $a$.

Only nonsingular square matrices $A$ have inverses. (A square matrix is *nonsingular* if and only if its determinant is nonzero.) When $A$ is nonsingular, its inverse, denoted $A^{-1}$, is unique and has the key property that $A \cdot A^{-1} = I = A^{-1} \cdot A$, where $I$ denotes the $n \times n$ identity matrix. The determinant of a square matrix $A$ (of any order) is a single scalar (number), say $a = \det(A)$. If this number is nonzero, the matrix is nonsingular, and accordingly has a reciprocal. Moreover, when $\det(A) \neq 0$, the inverse of $A$ exists and its determinant is the reciprocal of $\det(A)$. That is, $\det(A^{-1}) = (\det(A))^{-1}$.

A tiny example will illustrate these concepts, albeit somewhat too simplistically. Let

$$A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$$

Then, the determinant of $A$ is the number

$$\det(A) = a_{11}a_{22} - a_{12}a_{21}.$$ 

If $\det(A) \neq 0$, then

$$A^{-1} = \frac{1}{\det(A)} \begin{bmatrix} a_{22} & -a_{12} \\ -a_{21} & a_{11} \end{bmatrix}.$$ 

As a check, one can see that

$$A^{-1} \cdot A = \frac{1}{\det(A)} \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}.$$ 

This formula for the inverse of a $2 \times 2$ matrix is useful for hand calculations, but its generalization to matrices of larger order is far more difficult conceptually and computationally. Indeed, the formula is

$$A^{-1} = \frac{1}{\det(A)} \text{adj}(A),$$

where $\text{adj}(A)$ is the so-called adjoint (or adjugate) of $A$. The adjoint of $A$ is the “transposed matrix of cofactors” of $A$, that is, the matrix $B$ with elements $b_{ij} = (-1)^{i+j} \det(A(j,i))$.

One way to carry out the inversion of a nonsingular matrix $A$ is to consider the matrix equation $A \cdot X = I$, where $X$ stands for $A^{-1}$. If $A$ is $n \times n$, then this equation can be viewed as a set of $n$ separate equations of the form $Ax = b$ where $x$ is successively taken as the $j$th column of unknown matrix $X$ and $b$ is taken as the $j$th column of $I$ ($j = 1, \ldots, n$). These equations can then be solved by Cramer’s rule.
The concept of the inverse of a matrix is of great theoretical value, but as may be appreciated from the above discussion, its computation can be problematic, just from the standpoint of sheer labor, not to mention issues of numerical reliability. Fortunately, there are circumstances in which it is not necessary to know the inverse of an \( n \times n \) matrix \( A \) in order to solve an equation like \( Ax = b \). One such circumstance is where the nonsingular matrix \( A \) is lower (or upper) triangular and all its diagonal elements are nonzero. In the case of lower triangular matrices, this means (i) \( a_{ii} \neq 0 \) for all \( i = 1, \ldots, n \), (ii) \( a_{ij} = 0 \) for all \( i = 1, \ldots, n - 1 \) and \( j > i \). Thus, for instance

\[
A = \begin{bmatrix} 4 & 0 & 0 \\ 3 & -1 & 0 \\ 2 & 1 & 5 \end{bmatrix}
\]

is lower triangular; the fact that its diagonal elements 4, −1, and 5 are all nonzero makes this triangular matrix nonsingular. When \( A \) is nonsingular and lower triangular, solving the equation \( Ax = b \) is done by starting with the top equation \( a_{11}x_1 = b_1 \) and solving it for \( x_1 \). In particular, \( x_1 = b_1/a_{11} \). This value is substituted into all the remaining equations. Then the process is repeated for the next equation. It gives \( x_2 = [b_2 - a_{21}(b_1/a_{11})]/a_{22} \). This sort of process is repeated until the last component of \( x \) is computed. This technique is called forward substitution. There is an analogous procedure called back substitution for nonsingular upper triangular matrices. Transforming a system of linear equations to triangular form makes its solution fairly uncomplicated.

Matrix inversion is thought by some to be a methodological cornerstone of regression analysis. The desire to invert a matrix typically arises in solving the normal equations generated by applying the method of ordinary least squares (OLS) to the estimation of parameters in a linear regression model. It might be postulated that the linear relationship

\[
y = \beta_0 + \beta_1 x_1 + \cdots + \beta_n x_n
\]

holds for some set of parameters \( \beta_1, \ldots, \beta_n \). To determine these unknown parameters, one runs a set of, say, \( n \) experiments by first choosing values \( x_{12}, \ldots, x_{1n} \) and then recording the outcome \( y_i \) for \( i = 2, \ldots, n \). In doing so, one uses an error term \( u_i \) for the \( i \)th experiment. This is needed because for a specific set of parameter values (estimates), there may be no solution to the set of simultaneous equations induced by (1). Thus, one writes

\[
y_i = \beta_0 + \beta_1 x_{i1} + \cdots + \beta_n x_{in} + u_i, \quad i = 1, 2, \ldots, n
\]

The OLS method seeks values of \( \beta_1, \ldots, \beta_n \) that minimize the sum of the squares errors, that is \( \sum_{i=1}^{n} u_i^2 \). With

\[
y = \begin{bmatrix} y_1 \\ \vdots \\ y_n \end{bmatrix}, \quad X = \begin{bmatrix} 1 & x_1 & \cdots & x_n \\ 1 & \vdots & \vdots & \vdots \\ 1 & x_{n1} & \cdots & x_{nn} \end{bmatrix} \quad \text{and} \quad \beta = \begin{bmatrix} \beta \end{bmatrix}
\]

this leads to the OLS problem of minimizing \( Y'Y - 2XYX^T \). The first-order necessary and sufficient conditions for the minimizing vector \( \beta \) are the so-called normal equations \( XX^T \beta = XY \).

If the matrix \( XX \) is nonsingular, then

\[
\beta = (X'X)^{-1}X'Y.
\]

Care needs to be taken in solving the normal equations. It can happen that \( XX \) is singular. In that case, its inverse does not exist. Yet even when \( XX \) is invertible, it is not always advisable to solve for \( \beta \) as in (3). For numerical reasons, this is particularly so when the order of the matrix is very large.

INVESTMENT

There are three contexts of investment relevant to the social sciences. First, there is the authoritative investment of endowing a person with social and institutional authority, power, or privilege. Second, a financial investment consists of the production or purchase of an asset in order to obtain its yield, such as interest from bonds. Financial investments involve the exchange of one paper asset (money) for another asset—for example, stocks, bonds, and real estate. Third, an economic investment is the production of some new asset (new plant and equipment, expansion of inventories, new residential construction, reputation) or the creation of new laboring ability (human capital).

The methods of authoritative investing are delegation, inheritance, and usurpation. In a democracy, authoritative investment ends officials with authority in accord with the rules of elections and appointments to office. That authority vests the officials with power and privilege as legally delegated to them from the people, as ultimate sovereignty resides with the people. In a kingdom, royal authority is usually handed down by inheritance,
and inheritance also invests heirs with titles to private property. In a dictatorship, the chief of state invests himself or herself with ruling power, and criminals too vest themselves with power over their victims, such as when they illegitimately take property from their victims.

In finance and economics, investing is distinct from speculation. Speculators buy assets with the expectation of gaining due to shifts in supply and demand. Speculators buy shares of stock in a silver mining company if they expect the demand for the metal to increase. Investors buy the stock in order to obtain the dividends from the profits of the firm. The purchase can, of course, include both investment and speculation.

The yields of financial investments include interest, dividends, rentals, capital gains, and business profits. Dividends are a share of corporate profits from stocks or a mutual fund, while interest is obtained from loaned funds, such as bonds and savings accounts. Capital gains occur when an asset sells for a higher price than its initial price of purchase. The return to an investment can also be in the form of the retained earnings or profits of a corporation.

ECONOMIC INVESTMENT
Economic investment consists in the production of capital goods and the enhancement of human capital, the education, skills, and training obtained by workers. A capital good can be intangible, such as when a company invests in advertising in order to create goodwill and reputation capital. Human capital includes relationships with other persons, which is more specifically referred to as social capital. A person also invests in human capital to be a better consumer, such as learning music appreciation to enjoy symphonic music, which is more specifically referred to as cultural capital.

The inputs of production are classified as three “factors,” land, labor, and capital goods. Land means natural resources, existing prior to and apart from human action and its products. The purchase of land is a financial but not an economic investment. Capital goods, such as buildings, machines, and inventory, are products whose value is not yet consumed. Improvements to a site, such as clearing and leveling the surface, are included in capital goods.

A bond is a loan of funds to a borrower who pays interest for the duration or term and returns the funds when the bond matures. The bond might be used by the seller to produce capital goods, but the bonds are not in themselves produced goods and so are not an economic investment.

Technology is embedded in both capital goods and in human capital. If there is no change in technology, investments eventually have diminishing returns. Given a fixed area of land, fertilizer can increase the yield of a crop, but as more and more fertilizer is added, the extra amount of fertilizer provides a reduced amount of extra yield. If one keeps adding fertilizer, eventually the marginal product or extra yield becomes zero and then negative—too many cooks spoil the broth.

An increase in the amount of a variable input eventually yields diminishing returns when some other input is fixed. However, there can initially be increasing returns from more investment if there are network effects that increase the value of each good. For example, if fax machines are more widespread, then a machine has higher usefulness because it can send and receive messages from more units. Capital goods can also complement other investments so that there are at first increasing returns. But such increasing returns themselves eventually diminish. Much of the historic increase in productivity has come not just from an increase in the stock of capital goods but from better technology. There are no diminishing returns to better technology.

Both capital goods and human capital depreciate; they lose economic value due to “wear and tear” as well as from obsolescence and uncertainty. Gross investment is the total amount of production of capital goods and human capital, while net investment equals gross investment minus depreciation. In national income or output accounts, typically only investments in capital goods are included in the investment category in calculating gross and net domestic product.

EFFICIENT FINANCIAL MARKETS
The purpose of investment is to maximize future consumption, thus to obtain the greatest increase in future yields. The optimal investment has the highest risk-adjusted rate of return. Risk means the possibility of loss with a known probability. Uncertainty means the possibility of change with no known probability. The optimal investment has the greatest net present value, the value at present of a stream of future income minus the initial outlay and other costs, discounted by the relevant interest rate.

Even though subject to large fluctuations, financial markets tend to be rather efficient, meaning that the prices of financial assets encompass the known public information about the asset, the relevant industry, and the economy. The seller is pessimistic, believing the price will fall, and the buyer is optimistic, believing the price will rise. The price is the midpoint between the pessimists and the optimists. On the average, one who buys the stock will lose economic value due to “wear and tear” as well as from obsolescence and uncertainty. Gross investment is the total amount of production of capital goods and human capital, while net investment equals gross investment minus depreciation. In national income or output accounts, typically only investments in capital goods are included in the investment category in calculating gross and net domestic product.
Investment

will systematically profit from market timing or stock picking. It does imply, however, that riskier assets will normally have a higher return to compensate for the greater possibility of loss or of the greater fluctuations that make the price at some future date less predictable.

The theory of efficient markets for financial investments is called modern portfolio theory (MPT). It prescribes that an investor should seek no more than to match the averages of the various sectors of financial markets. However, the relevant knowledge has to be utilized by some investors or speculators in order to set the efficient price in the first place. Research into companies, industries, and the economies must offer some reward, and in an efficient market this reward would be commensurate with other gains.

Efficient markets also do not preclude some financial analysts from having insights and analysis superior to those of others in some types of markets and economic conditions. Not only is there great uncertainty about future economic variables, such as inflation and interest rates, but there is also a lack of consensus about many aspects of economic theory, such as business cycles.

SAVINGS AND INVESTMENT

Savings equal income minus consumption. In economics, consumption means the using up of economic value, like fire consuming wood. Production means the creation of economic value. The consumption of a house consists in its depreciation. The purchase of a car has the same economic characteristics; the car is an investment, and its consumption is the depreciation. From the economic point of view, all goods that one buys are investments until they are consumed, although in national income accounts, outlays other than for a house are counted as consumption.

Savings are either invested or kept in money. Few people normally hoard large amounts of cash, so ordinarily people save money in a financial institution, such as a bank or a money market fund. These institutions in turn loan out their money. Money borrowed for consumption offsets some of the money saved, and the rest is spent for investment. Thus in general the net savings of households is either invested or kept as money in the banking system. Banks are legally required to have a small portion of their deposits held in reserve, and they loan out the excess reserves.

Investment comes from savings, but the amounts households plan to save do not necessarily equal the amounts that investors seek to borrow. If investors seek to borrow more than what is available from savings, then the market rate of interest will rise, reducing the amount of intended borrowing while increasing the amount of savings. If the supply of savings increases, then interest rates fall as bankers seek to loan out the excess reserves. The market rate of interest thus has an important role in the economy: it equilibrates savings and investment so that the quantity of loanable funds supplied by savings equals the quantity demanded for investment by borrowers.

The total savings in the economy also includes government savings, government revenues minus government spending. A government deficit that is used for consumption creates negative savings, a reduction in national savings. Government bonds can compete with corporate bonds, raising interest rates and “crowding out” private investment that would have taken place unless the funds are borrowed from abroad or private savings increase. Unless the deficit spending is used for productive investments, such as infrastructure, the government deficit can burden future generations by reducing private investment and also by making future taxpayers pay interest on debt that does not benefit the present generation.

INVESTMENT AND THE BUSINESS CYCLE

Investment fluctuates much more than consumption. Major changes in investment drive the business cycle as recessions occur after a large decline in investment. Investment declines because entrepreneurs expect lower profits, and profits usually decline either because costs have gone up or because the demand for goods is expected to fall. In some economic models, the accelerator principle asserts that investment depends on the annual increase in output and the capital needed to produce the increase. The more fundamental explanation is that savings, interest rates, and expectations about the future determine the amount and the mix of investment.

Lower real interest rates induce more investment in fixed capital goods, such as real estate construction. When the monetary authority expands credit by injecting money into the banking system, the interest rate is lowered as the banks seek to lend out the extra money. Later, to prevent excessive inflation, the monetary authority then reduces the rate of money growth, and interest rates go back up. Investments profitable at the previous lower interest rates are no longer profitable, reducing investment and also wasting capital that would have been better invested in goods with a faster turnover.

Meanwhile the lowered rate of interest also makes it attractive to invest and speculate in real estate. Much of the benefit of economic growth is soaked up by higher rentals and land values due to the fixed supply of land and implicit subsidy to land values from public works not financed from the generated rents.

Speculative demand adds to the demand for use, pulling up real estate prices. At the peak of the boom, higher interest rates plus higher real estate costs diminish
profits, and industries such as construction slow down. The diminishing investment reduces demand for other goods, and the economy falls into a recession. Real estate prices and interest rates then fall, and the reduced costs eventually lead entrepreneurs to invest again, and then the economy recovers.

TAXATION, REGULATION, AND INVESTMENT

Income taxes reduce investment by taxing the interest, dividends, profits, and capital gains from savings, enterprise, and investment. The effect is more severe when, as in the United States, the income tax is on nominal gains and nominal depreciation, ignoring inflation, thus taxing the principal as well as the gain. This excess burden has been recognized by providing for tax sheltered savings, such as individual retirement accounts (IRAs), by lower tax rates on capital gains, and by investment credits for businesses. Nevertheless, much of investment remains subject to taxation. Sales and value-added taxes have similar excess burdens. Some economists advocate shifting public revenues to pollution charges, user fees, and rents of natural resources to avoid excess burdens on investment in both capital goods and human capital.

Regulations can enhance markets, such as when they prevent fraud, but they also impose costs similar to taxation. Excessive restrictions and reporting costs can create a deadweight loss similar to taxation, a reduction of investment not offset by social benefits.

INVESTORS

The term investor is widely used not only by economics and finance academics and professionals, but also by ordinary people. An investor is an individual or an organization that makes an investment. The term investment itself is interpreted differently by the common public and finance professionals on the one hand, and by academic and professional economists on the other.

INVESTMENT IN ECONOMICS

LITERATURE

In economics, investment refers to resources used to increase capital stock. The items included are expenditure on:

1. Plants (machines) and equipments.
2. Structures (factories, office building, etc.).
3. Inventories (of finished and unfinished goods).
4. New residential houses.

Moreover, the above items must be the result of current production. Suppose, for example, that General Motors (GM) spends $20 million in 2007 to build a new automotive factory to produce cars based on alternative fuel. GM will be considered by economists to have invested $20 million in 2007. This investment will add to the capital stock (the accumulated value of all capital: plants, equipment, buildings, factories, etc.) owned by GM at the end of 2006. However, if GM buys in 2007 a factory that Ford had utilized through 2006, economists will not consider the transfer of the automotive factory as investment from the nation’s point of view. This is because the factory Ford sold is not new—it is not the result of production in 2007. The purchase of the Ford factory by GM merely reflects a change in ownership of existing capital. Similarly, if you buy a five-year-old mansion for $7.5 million, it is not considered investment by economists, but buying a new mansion will be counted as investment.

Notice that even long-lasting new things that consumers buy are not counted in investment, except for new houses. Suppose you spend $150,000 to buy a new seaworthy boat, and $90,000 to buy a new condominium. The condominium will be counted as investment, but not the boat (which is actually more expensive). The boat is considered a consumption item, not an investment item. However, if a business had bought the same new boat to operate a sightseeing tour, it would be considered an investment item.

Economists also distinguish between net and gross investment. This distinction is necessitated by the fact that there is a wear and tear of capital stock as it is used in the production process—that is, the capital stock depreciates. Thus, investment that includes depreciation is called gross investment, and after the value of depreciation is subtracted from the gross investment, the resulting amount is the net investment. The nation’s capital stock during any year rises by the extent of net investment. The part of cur-
rent income that consumers do not consume is called saving. It is this saving that largely finances investment by businesses, and leads to an increase in the capital stock of the nation. The widely used term capitalism is based on the notion of an economic system that is based on ownership of capital.

INVESTMENT IN FINANCE
LITERATURE AND ORDINARY USE
The use of the term investment in finance and by ordinary people refers to buying an asset. The asset can be a financial instrument, commonly called a security (such as stocks, bonds, and a certificate of deposit or CD) or a real object (such as real estate, gold, and paintings).

To understand the notion of an investor, one should look at the various types of investments that he or she could invest in. The choice of the investment vehicle by an investor indicates how much risk the investor is willing to take. The following describes the major categories of investment or assets.

Equity or stocks represent ownership in a company or business. If you own 10 percent of GM stocks, you literally own 10 percent of GM. Equities constitute a major asset class. Stocks are considered risky in the sense that you can lose money if their value falls or if the company goes bankrupt. Stock investors of Enron, a U.S. public corporation that went bankrupt in 2001, were left with stocks that were worthless. Ownership of stocks can change frequently—they are traded on stock exchanges or computer-linked systems.

Bonds are the second most prominent asset class. A bond, also called a debt security, represents a loan made by an investor to a borrower. Normally, a bond has a maturity period of one to thirty years. The maturity period of a bond indicates in how many years the loan is due to be repaid. Thus, an investor holding a ten-year GM bond will receive periodic interest payments (usually twice a year) from GM and will receive the principal amount loaned at the end of the ten-year period. There is risk associated with bonds as well, because the borrower may be unable to pay interest and the principal on time or not at all. This is called default risk. If a company goes bankrupt, the bondholders as lenders have claims on the company’s assets. The company’s assets when sold may provide to the bondholders as lenders a claim on the company’s assets when sold. Therefore, bondholders as lenders have claims on the company’s assets when sold. Because fewer things can go wrong in a year, a money market instrument is less risky than stocks or bonds. In fact, the money market is a way for an investor to hold cash (a liquid or cashlike asset). By investing in money market instruments, an investor has a relatively riskless asset, while still earning some interest income.

In addition to the preceding three widely utilized assets, there are other assets that an investor may choose to invest in. These include (among others): real estate (ownership of land or buildings); foreign exchange or currency (U.S. dollars, yen, euros, etc.); commodities (precious metals, crude oil, soybeans, etc.); derivatives (such as options and futures—these financial instruments are derived from or based on other financial securities); and works of art or other collectibles.

To distinguish between the notion of investment as used in finance and economics, investment in items such as plants and equipment is called simply investment, whereas investment in financial securities is called portfolio investment.

The choice of security indicates the extent of risk an investor is willing to take—the greater the risk, the greater the expected return on the investment. A risk-averse investor tries to diversify within an asset class or across asset classes.

RELATED TERMS IN USE
One will encounter a large number of terms in the context of discussing an investor or an investment. The following provides a nonexhaustive list of terms that have not been mentioned above: individual investors (including trusts on behalf of individuals, and umbrella companies formed to pool investment funds from two or more investors), angel investor (an affluent person who provides capital for a business start-up), amateur investor (often indicating an individual who invests blindly or is influenced by romantic notions rather than hard facts), venture capital funds (which provide start-up capital in lieu of a share of the business), financial intermediaries, banks, mutual funds, pension funds, hedge funds, insurance companies, investment banks, investment trusts (such as real-estate investment trusts), and regulatory institutions (such as the U.S. Securities and Exchange Commission or SEC).

BIBLIOGRAPHY
INVESTORS, INSTITUTIONAL

Institutional investors are professional fiduciary entities managing investment portfolios on behalf of their clients as well as for their own proprietary accounts. The major groups include mutual funds, independent investment advisors, banks, insurance companies, foundations, endowments, pension funds, and, more recently, hedge funds.

Mutual funds are traditional investment companies managing investment portfolios for funds’ shareholders. Independent investment advisors are typically associated with large diversified financial institutions (e.g., Lehman Brothers, Bear Stearns) and can invest for their own proprietary accounts as well as manage portfolios for their clients (such as wealthy individuals, pension funds, endowments, etc.). Investments managed by banks are mostly limited to trusts and some pension funds. Insurance companies invest primarily in fixed-income securities. University endowments and charitable foundations are mostly concerned with capital preservation and often invest all or most of their investment portfolios to professional money managers (e.g., independent investment advisors). Hedge funds are mostly unregulated investment vehicles, which are restricted to qualified wealthy investors and are not required to register with the Securities and Exchange Commission or to report their ownership positions.

Since the 1950s, institutional investing has played an increasingly important role in global financial markets. Professional investors and money managers of the twenty-first century have control over a significantly larger asset base than their colleagues thirty or forty years ago. According to quarterly institutional filings with the Securities and Exchange Commission (Form 13F), both the number of institutional entities and aggregate assets under their management experienced tremendous growth during the second half of the twentieth century. According to Paul Gompers and Andrew Metrick (2001), reported U.S. holdings of large institutional investors (excluding hedge funds) grew from $375 billion in 1980 to $3.98 trillion in 1996. Institutional ownership of the U.S. equity markets grew from less than 10 percent in 1950 (estimated by Friedman 1996) to 27.6 percent in 1980 and to over 61.2 percent in 2005. According to the Conference Board, in 2005 large U.S. institutions controlled over $24 trillion in assets (excluding hedge funds). Independent investment advisors have experienced the greatest growth of all institutions. In 1997 there were roughly six times more independent investment advisors than in 1983 (1,128 versus 195). Most recently, hedge funds outpaced other types of institutions in number of entities, which skyrocketed from about 530 in 1990 to over 7,000 in 2007 (excluding funds of funds), and it is estimated that in 2007 hedge funds controlled between $1.5 to $2.0 trillion assets under management worldwide.

The growth in institutional investments can partially be attributed to the worldwide proliferation of public and private pension plans (e.g., Government Pension Investment in Japan, ABP in Netherlands, CalPERS in the United States) and tax-deferred retirement savings plans (e.g., 401(k), 403(b), IRA). Large institutional investors became active advocates of shareholder interests and corporate monitors (Hartzell and Starks 2003). Blockholders and other large owners play an increasingly important role in corporate governance as well as proxy battles. While some institutional investors are very independent in their voting decisions (e.g., CalPERS), others often rely on recommendations of Institutional Shareholder Services.

For their professional management, institutions earned a reputation of “smart money.” In fact, some institutional investors appear to be able to predict future negative events, such as class-action shareholder litigation (Barabanov et al. 2007) and may also benefit through informed trading at the expense of less-sophisticated individuals. Investors, for example, institutions capture postearnings announcement drift in stock prices (Cohen et al. 2002), participate less frequently in lower-quality seasoned equity offerings (Gibson et al. 2004), select stronger initial public offerings (Field and Lowry 2005), do a better job interpreting both analyst recommendations (Mikhail et al. 2005) and earnings announcements (Ali et al. 2004), and do not trade as often as individuals on misleading “pro forma” earnings (Bhattacharya et al. 2005). Sergey Barabanov and colleagues (2007) show that information advantage of institutional investors stems mostly from their skills in analyzing public quantitative information. Unlike some individuals, institutions seem to refrain from trading on illegal insider information.

Good performance of institutional portfolios is driven by institutions with a short-term performance focus, such as independent investment advisors and mutual funds (e.g., Barabanov and McNamara 2007), whose compensation is based primarily on performance relative to their peers and respective benchmarks. Unlike
institutions with a long-term focus (banks, insurance companies, foundations, and endowments), short-horizon institutions possess private information about long-term earnings, which is reflected in short-term prices (Ke et al. 2006). Mutual funds and independent investment advisors are typically more aggressive than banks, insurance companies, and endowments. Consequently, mutual fund managers often choose to invest in relatively risky securities with high levels of ownership turnover (Bennett et al. 2003). While 77 percent of mutual fund managers have been found to be return momentum traders (Grinblatt et al. 1995), bank-managed trusts and pension funds, in contrast, are typically more conservative in their investment policies and do not strongly pursue potentially destabilizing trading behavior such as herding (mass buying or selling of a particular asset) or momentum trading (e.g., Lakanishok et al. 1992). Because they are subject to the American Bankers Association’s Model Prudent Man Investment Act and the American Law Institute’s Restatement of Trusts, managers of bank trusts and bank-managed pension funds are personally liable and aim to ensure that their investments are considered prudent by courts should any litigation arise (Longstreth 1986; Del Guercio 1996). Insurance companies invest only a small portion of their assets in equities and prefer low volatility of returns (Badrinath et al. 1996). Endowment managers display conservative behavior as they typically do not have performance incentives for high relative returns, but may suffer highly negative publicity in the case of poor performance (Brown 1999).

Historically, institutions preferred to invest in large capitalization companies with better visibility and transparency of earnings, revenues, and management, wider analyst coverage, and low transaction costs (e.g., Gompers and Metrick 2001; Falkenstein 1996; O’Brien and Bhushan 1990). With increasing competition among professional money managers, institutional preferences have shifted toward smaller stocks, where they can achieve more benefits from their informational advantage (Bennett et al. 2003), as well as new asset classes (e.g., private equity, venture capital, hedge funds) and developing and emerging markets.

Institutional participation enhances market liquidity, efficiency, transparency, and corporate governance both in developed and emerging markets. The information acquisition activities of institutional investors, for example, stimulate the speed of adjustment to new information (Sias and Starks 1997) and reduce information asymmetries between insiders and capital markets (Szewczyk et al. 1992). Even though aggregate institutional ownership data provides evidence of institutional herding and momentum trading, this behavior appears to be exhibited less by institutions than by individuals and is attributed mostly to trading by mutual funds and independent investment advisors. Overall, institutional investors help mitigate potential instabilities in financial markets by facilitating efficient allocation of resources through transfers of risks and access to capital.

Unemployment is a labor-market state in which a person is without a job and is actively looking for work. There is nothing, however, in this definition to suggest whether the person is unemployed voluntarily or involuntarily. Prior to the publication of John Maynard Keynes’s General Theory of Employment, Interest, and Money in 1936, mainstream economists within the “classical” (or, more correctly, the “neoclassical”) tradition categorized unemployment into two major types, both relating to the supply side of the labor market. Unemployment could be conceived as a short-term equilibrium phenomenon arising from the choice of workers to participate in the labor market and engage voluntarily in job search—a situation in which individuals could find themselves temporarily “between jobs” and in a state of “frictional unemployment.” On the other hand, unemployment was also construed as a disequilibrium phenomenon arising from the existence of institutional barriers in the labor market, such as trade unions, government fiscal and monetary policy, and the market power of firms, which were presumed to prevent the downward adjustment of real wages to shortfalls in labor demand. In this latter case, individual workers could be said to be involuntarily “off their labor supply function” because of labor-market imperfections. If only wages could be left to adjust freely to fluctuations in labor demand and supply, it was believed that competition would clear the labor market and result in a state of equilibrium at full employment compatible with the presence of only voluntary and/or frictional unemployment. From this orthodox analysis, it ensues that the existence of job scarcity in the labor market could never be a long-term phenomenon, unless institutional forces persist to prevent market clearance.

Keynes challenged this particular conception of the labor market. While recognizing the existence of frictional unemployment, he questioned the neoclassical view of unemployment as a supply-side phenomenon resulting from wage rigidity. For Keynes, the labor market cannot be analyzed in isolation but, instead, is itself dependent on conditions in the overall product market. Through derived demand for labor, it is the state of aggregate effective demand for goods and services in the economy that ultimately sets the constraint on the level of employment, and not the lack of a mechanism of competitive downward wage adjustment in the labor market that generates unemployment. Furthermore, even the most unlikely situation, where workers accept a reduction of their money wage, would not necessarily guarantee a reduction of their real wage. Indeed, Keynes argued that because of the negative feedback effect on current and expected future sales proceeds, a cut in wages could only make matters worse and result in even higher (rather than lower) unemployment.

Keynes dubbed this type of unemployment endemic to a demand-constrained economy stuck in a state of underemployment equilibrium—“involuntary unemployment.” In chapter 2 of The General Theory, Keynes provides a test for the existence of involuntary unemployment:

*Men are involuntarily unemployed if, in the event of a small rise in the price of wage-goods relatively to the money wage, both the aggregate supply of labour willing to work for the current money-wage and the aggregate demand for it at that wage would be greater than the existing volume of employment.*

(Keynes 1936, p. 15, emphasis in original)
In short, if the gap between labor demand and supply persists with a fall in the real wage (brought about by a rise in prices), individual job seekers would be considered by Keynes to be in a situation of involuntary unemployment—a state associated with a nonzero elasticity of employment and output with respect to changes in aggregate demand (Darity and Young 1997, p. 26). In highlighting a particular causal sequence—going from changes in prices (for a given money wage) to a fall in real wages—he asserted that the fundamental cause of involuntary unemployment is job scarcity and the inadequacy of existing demand, not workers’ obstinacy in resisting a cut in their real wage, as maintained by neoclassical economists.

Soon after the publication of the General Theory, numerous economists began to reinterpret Keynes’s analysis. Influenced by Keynes’s own empirical recognition of the stickiness of money wages in chapter 2 of the General Theory and the assumption of the money-wage unit as a mere historical datum, beginning with Franco Modigliani (1918–2003) in 1944 writers began to postulate a labor-supply function that is perfectly elastic up to full employment at a historically given money wage. Consequently, they began to explain involuntary unemployment as the result of workers’ resistance to money wage adjustment because of irrational behavior (sometimes referred to as “money illusion”). A whole generation of Keynesian economists, such as Modigliani and James Tobin (1918–2002), from the 1940s to the 1960s built macroeconomic models to explain unemployment on the basis of this static wage rigidity assumption, despite the fact that Keynes himself had rejected wage stickiness as an explanation of involuntary unemployment. In the early post–World War II (1939–1945) years, however, there emerged a related, yet competing strand of thought, commencing in 1948 with the work of Don Patinkin (1922–1995), who reinterpreted a state of involuntary unemployment as a dynamic disequilibrium due not to exogenous wage fixity but to the sluggish adjustment of wages to labor market pressures. By the late 1960s and early 1970s this work had given rise to the so-called disequilibrium theory of involuntary unemployment, associated with such writers as Robert Clower, Robert J. Barro and Herschel I. Grossman, and Edmond Malinvaud. Whether framed in an equilibrium (static) or disequilibrium (dynamic) setting, in both strands of analysis the cause of involuntary unemployment was the lack of adequate downward adjustment of wages and prices to shortfalls in aggregate effective demand.

During the 1970s and 1980s both of these approaches quickly succumbed to the criticisms of Milton Friedman, Robert E. Lucas, and the new classical economists because of problems of logical inconsistency and insufficient microeconomic grounding. According to the monetarists and the new classical economists, one cannot develop theories of the economy that assume rational behavior for an economic agent in the product market (say, as consumer) but irrational behavior as supplier of labor services in the labor market, as the earlier Keynesian writers had surmised. Moreover, because of their assumption of continual market clearance, new classical economists easily eschewed the sluggishness argument of the disequilibrium theorists. Hence, new classical economists such as Lucas were able to conclude that it was not possible, “... even in principle, to classify individual unemployed people as either voluntary or involuntary unemployed ...” (Lucas 1981, p. 243).

Despite the attempt of new classical economists to purge involuntary unemployment from the vocabulary of modern macroeconomics, the concept of involuntary unemployment has shown resilience in the hands of both New Keynesian and post-Keynesian economists over the last two decades. Numerous New Keynesian models have been developed within a choice-theoretic microeconomic framework compatible with neoclassical theory. Particularly noteworthy is the abundant literature on implicit contracts and on efficiency wages that reconcile wage rigidity and involuntary unemployment and now see the existence of the latter as a Pareto-efficient solution in the labor market (see Davidson 1990). In contrast, post-Keynesian models that follow more closely Keynes’s original insights emphasize the macroeconomic basis of their theories of involuntary unemployment in which wage rigidity plays no role, even though some are founded on microeconomic foundations of Marshallian pedigree (see Davidson 1994, chapter 11).

The notion of involuntary unemployment is at the core of Keynesian theory. Ever since the publication of Keynes’s General Theory more than seventy years ago, this concept has been plagued with controversy and has remained a wedge that separates those who believe that a capitalist economy is prone to systemic instabilities, as reflected in the existence of periodic recessions accompanied by mass unemployment, from those who believe in the strength of the self-correcting forces in market economies, in which actual unemployment is conceived as a mere short-term transitional phenomenon gravitating around some stable, long-term “natural” rate of unemployment. Although today one could find some strong Keynesian sympathizers who might even be prepared to do away with the concept of involuntary unemployment because of conceptual difficulties and refer, instead, to some less controversial notions of underemployment (see De Vroey 2004), the former concept still remains very deeply ingrained in the professional vocabulary of many contemporary economists.

IQ CONTROVERSY

Four issues dominate debate about IQ: how intelligence should be defined and measured; genetic versus environmental factors; group differences; and the degree to which IQ stratifies individuals and groups by class and occupation.

INTELLIGENCE DEFINED AND MEASURED

Science suggests a distinction between pre-theory and post-theory definitions. The transition from classical to modern astronomy marked a shift from one pre-theory concept to another, that is, from the notion that planetary motions should be reduced to circles to the notion of forces that are a function of mass and distance. The latter notion was more fruitful but had no advantage over the former in terms of clarity or quantification. Adding those attributes is the job of competing theories, each of which transforms the broad pre-theory concept into a post-theory concept. René Descartes said the sun turned on its axis and created a whirlpool; Isaac Newton said the sun attracted the planets in proportion to its mass and inversely as the distance squared; Albert Einstein said the sun warps space (and time) in its vicinity, and the planets follow the path of the resulting curved space. All accepted that they should pay attention to mass and space, but none thought that this concept should hand them specificity and measurability—that was their job.

Arthur Jensen (1998) gave up using the word intelligence because it lacked the specificity and measurability of his theory-embedded concept of g. He was asking a pre-theory concept to exhibit the characteristics that only a post-theory concept can have. In fact the architects of IQ tests have a perfectly satisfactory pre-theory concept to guide them: Intelligence is greater the greater the speed and quality of learning (where all have an equal chance and are positively disposed); and intelligence involves solving problems and therefore requires not only on-the-spot acuity but also working memory, information processing, a reasonable vocabulary, a reasonable fund of general information, basic numeracy, and so forth. IQ tests such as the Wechsler Intelligence Scale for Children (WISC) incorporate this notion of intelligence with subtests (Vocabulary, Information, and Coding), whose names betray their origins.

This concept was formulated in modern industrial societies. Those assessing intelligence in other social contexts should consult the Piagetian anthropologists. Some theorists recommend a broader concept. Robert Sternberg (1988) says we need not only analytic skills but also creativity and the practical intelligence to deal with problems such as a difficult coworker. Howard Gardner (1993) adds musical talent and athletic ability to the list of “intelligences.” Daniel Goleman (1995) includes the character traits, such as empathy, temperance, and self-esteem, needed to solve “human” problems.

In response we need only amplify the pre-theory concept to make it plain that “speed and quality of learning” and “problem-solving skills” must be broad enough to allow various thinkers and students of various cultures to evidence just what skills and traits are relevant to socially valued problem solving. These empirical questions will not be settled by debate about whether we have an “adequate” definition of intelligence.

GENES VERSUS ENVIRONMENT

Twin studies show that genes are powerful and environment weak in affecting individual differences in intelligence. Massive IQ gains over time (average IQ has risen as much as 20 points in a single generation) suggest environmental factors of enormous potency. To resolve this paradox, we must distinguish between the dynamics of individual differences within a cohort and trends between cohorts.

As an example, John and Joe are identical twins separated at birth. Identical genes make them both taller and quicker than average. John goes to school in one city, plays basketball a bit better on the playground, catches the eye of the grade school coach, plays on a team, and goes on to play in high school, where he gets really professional coaching. Joe goes to a different school, in a city 100 miles

IQ Controversy

away. However, precisely because his genes are identical to John’s, precisely because he is taller and quicker than average to the same degree, he is likely to have a similar life history. In contrast, Mark and Allen are separated twins whose identical genes make them both a bit shorter and stodgier than average. They too have similar basketball life histories, except in their case both play little, develop few skills, and become mainly spectators.

Turning to IQ, one child is born with a slightly better brain than another. Which of them will tend to like school, be encouraged, start haunting the library, get into top-stream classes, and attend a university? And if that child has a separated identical twin who has much the same academic history, what will account for their similar adult IQs? Not identical genes alone—the ability of those identical genes to co-opt environments of similar quality will be the missing piece of the puzzle.

Between generations, the effect of environment is hugely potent because persistent environmental factors seize control of a powerful instrument that multiplies their effects. With the invention of television, basketball got a mass audience, and the pay of professional players soared. Wider and keener participation raised the general skill level, and that higher average performance fed back into play. Those who learned to shoot baskets with either hand became the best—and then they became the norm—which meant you had to be able to pass with either hand to excel—and then that became the norm—and so forth. In other words, rising average performance became a potent causal factor in its own right, and there was a huge escalation of basketball skills in a single generation.

As for IQ, after the Industrial Revolution, when a grade school education became the norm, middle-class aspirations dictated a high school diploma. When a high school diploma became the norm, people wanted a university education. Economic progress created new expectations about hands-on parenting, highly paid professional jobs in which we are expected to think for ourselves, and more cognitively demanding leisure activities.

No one wants to seem deficient as a parent, unsuited for promotion, or boring as a companion. Everyone responds by enhancing his or her performance, which pushes the average higher, so all respond to that new average, which pushes the average higher still.

The paradox is resolved. Within a generation, genetic differences use feedback processes to magnify IQ differences between individuals. Between generations, environmental trends use feedback processes to escalate mean IQ over time. It all depends on whose hand is on the throttle.

This has implications for interventions designed to raise IQ, which must be persistent, or the tendency of genes to match environmental quality will slowly erode their effects. However, genes do not pin each of us to a place on the IQ hierarchy. Similarly people can improve on their physical endowment for running. Either circumstances force you to train throughout life, or you develop a love for running and train without compulsion. There will be some who beat me even though I train more than they do, but I can run rings around every couch potato within twenty years of my age.

GROUP IQ DIFFERENCES

Factor analysis suggests two sorts of IQ differences: differences between racial or ethnic groups, and differences between groups separated by social trends over time. Often subjects take a whole battery of IQ tests; for example, the ten subtests of the WISC measure cognitive skills ranging from information, vocabulary, and arithmetic to coding, solving puzzles, and seeing what concepts have in common. Subjects who do better than average on one tend to do better than average on all. Factor analysis measures this tendency and calls the result the “g factor.” Above-average subjects open up a wider gap over the average person on some tasks than on others, and these tend to be more cognitively complex. So cognitively complex tasks have higher “g loadings” than simple tasks, such as rote memorization. This is why Jensen thinks g a good measure of intelligence. It identifies those tasks on which intelligent people tend to do best. Some people excel to an unusual degree on verbal, or mathematical, or spatial tasks, and factor analysis also measures these tendencies and calls them “subordinate factors.”

American whites outscore blacks by 5 to 17 IQ points, and the gap increases from ages five to twenty-five. The subtest differences are factor invariant, that is, the racial score gaps tend to mimic the g loadings. Indeed there is a tendency for the gaps to widen the higher the g loading. However, when a generation outscores the last by 9 to 20 points, subtest differences are wildly at variance with factor loadings. The Vocabulary and Similarities subtests are close for g loadings, and yet the latter shows a 24-point gain compared to a 2-point gain.

Another sports analogy: Factor analysis of the ten events of the decathlon produces a g because at a given time and place, someone who is superior on one is better on all. Different events get various g loadings because superior athletes perform further above average on some than others. The 1,500 meters has a low loading because endurance is not very necessary in the other events. The 100 meters, the hurdles, and the high jump all have large and similar loadings. However, over time social priorities change. People become obsessed with the 100 meters (which determines the “world’s fastest human”). Over thirty years, performance escalates by a full standard deviation (SD) in the 100 meters, half an SD in the hurdles, and not at all in the high jump. The trends do not mimic
the relative $g$ loadings of the “subtests.” After thirty years, we do another factor analysis, and lo and behold, $g$ is still there. Although average performance has risen “eccentrically” on various events, superior performers still do better than average on all ten events and are about the same degree above average on various events as they were thirty years before.

Athletic coaches lament that everyone prefers the 100 meters and do not take other events seriously. They point out that sprint speed may be highly correlated with high jump performance, but past a certain point it is actually counterproductive—if you hurl yourself at the bar at maximum speed, your forward momentum cannot be converted into upward lift, and you will time your jump badly. They are not surprised that increased sprint speed has made some contribution to the hurdles, because speed between the hurdles is important. But it is only half the story: You have to control your speed so that you take the same number of steps between hurdles and always jump off the same foot.

In the WISC subtests the $g$ factor was a bad guide to which real-world cognitive skills are merely correlated and which are functionally related. Assume that science has engendered a sea change. Once we used logic primarily with concrete referents: All toadstools are poisonous; that is a toadstool, therefore it is poisonous. Now we use logic with the abstract categories provided by science: Only mammals bear their young alive; rabbits and dogs both bear their young alive; therefore they are both mammals. This would bring huge gains over time on the similarities subtest, which demands that we classify in terms of abstractions.

But on subtests that sample the core vocabulary and information of everyday life, this causal factor would not trigger large gains. Indeed changing social priorities might include both a more scientific outlook and less time for reading, in which case huge gains on the Similarities subtest would be accompanied by losses on the Vocabulary and Information subtests. Real-world functional skills would assert their autonomy from one another and from the straitjacket of factor loadings. IQ differences are not factor invariant, but they are not trivial. They just have a different real-world significance.

When blacks gained 5.5 IQ points on whites between 1970 and 2000, the gains were not $g$ gains. Gains on various subtests did not tally with their $g$ loadings. Despite this, the 2000 IQ gap between the races was still a $g$ gap and had diminished by 5.13 points, largely because the difference in $g$ loadings on WISC subtests are small. If further environmental progress eliminates the black-white IQ gap, blacks will probably match whites for $g$ as well as for IQ.

Debate about whether the black-white IQ gap is genetic or environmental has shifted. It used to cite the work of Klaus Eyferth, who found that the offspring of black American soldiers in Germany had no IQ deficit; Sandra Scarr, Richard Weinberg, and Irwin Waldman (1993), who found that black children adopted by white parents show only small gains at maturity; and Jensen (1998), who emphasized that the racial gap was a $g$ gap. Now the black loss of ground on whites with age is central. After all, the gap is only 4.6 points at age four (perhaps 1 point at nine months). If the decline with age were arrested, that would be that. Few would argue that the races enjoy complete environmental equality at present. Adherents of environment and genes both believe they can supply the causes of the decline.

### STRATIFICATION BY IQ

There are IQ thresholds for various occupations. Someone with an IQ below 100 is unlikely to qualify as a professional, manager, or technician.

Blacks and whites have similar thresholds. Therefore as long as their IQ gap persists, only the top one-sixth of blacks will qualify for jobs open to the top one-half of whites. Chinese Americans develop a character structure such that they can qualify for these occupations with an IQ threshold of 93. They also capitalize more effectively on the pool of those who score above this threshold, and as a group they behave as if they had a bonus of 20 IQ points. Despite similar IQs, females outperform males academically. At age seventeen, the girl’s median for written composition is at the boy’s 75th percentile. The girl’s median for reading is at the boy’s 67th percentile. Female advantage in academic achievement does not translate into a better occupational profile because of larger investment in child rearing.

Measures of self-discipline, such as saving money, are better predictors of grades than is IQ. Noncognitive factors, such as self-esteem and the degree of control people feel they have over their fates, are as important as cognitive skills in predicting not only wages and productivity but also teenage pregnancy, smoking, marijuana use, and criminal behavior. When black women are matched with white women with the same IQs, the black women are about three times as likely to be single parents, have been on welfare, and be in poverty. They suffer from a marriage market in which for every 100 black women of marriageable age, there are only 57 black men in steady work.

Some predict a nightmarish scenario. As industrial societies equalize opportunity and environments, only talent will count, and because genes drive individual differences in talent, good genes will go to the top and we will have a caste system based on “merit.” The least successful will become a permanent underclass. Because this scenario assumes people driven by wealth and status, it seems problematic that such people will finance the equalization of
environments. If an underclass does develop, their children will hardly profit from equal environments and opportunities. A meritocracy that engendered an underclass would be inherently unstable. Social stratification by genes or IQ is unlikely to make a radical break with the past.

IRAN-CONTRA AFFAIR

The Iran-Contra affair is a political scandal that occurred during the second term of Ronald Reagan’s (1911–2004) presidency. The scandal encompassed two secret programs coordinated by the National Security Council: (1) the sale of arms to Iran in contravention of U.S. policy and without congressional approval; and (2) the diversion of the proceeds from the weapons sales to support the activities of the anticommunist Contra rebels in Nicaragua, in violation of the 1982 Boland Amendment ban on military aid.

In October 1986 the government of Nicaragua shot down an American cargo plane carrying military supplies to Contra forces and captured an American employee of the Central Intelligence Agency. One month later, a Lebanese news magazine, Ash-Shiraa, revealed a secret program for the sale and transfer of military weapons to Iran in exchange for the release of U.S. hostages being held in Lebanon. Iran, at war with Iraq for six years and in need of American-made military equipment, purchased weapons in exchange for securing the release of American hostages. In response to these reports, President Reagan denied on national television that any arms had been traded to Iran, but one week later he admitted the Iranian arms transfer occurred.

It was quickly discovered that the United States had begun negotiating with Iran in secret, while the country was allegedly neutral in the Iran-Iraq War and maintained a policy against trading for hostages. In early 1986 Reagan's first national security adviser, Robert McFarlane, and his successor, Admiral John Poindexter, shipped weapons, including surface-to-air and antitank missiles, from Israel to Iran's revolutionary government without congressional approval, diverting the proceeds from the sales to the Contras, who sought to overthrow the Sandinista government in Nicaragua. Reagan's attorney general, Edwin Meese, was directed to investigate the arms sales and requested the appointment of an independent counsel. In December 1986 Lawrence E. Walsh was appointed to investigate the weapon sales and the process by which the proceeds were diverted to the Contras.

In December 1986 President Reagan appointed former Republican senator John Tower (1925–1991) to investigate the Iran-Contra affair and issue a report on the actions of the National Security Council. The Tower Commission Report found Poindexter responsible for authorizing the illegal sale of arms to Iran in exchange for the release of the U.S. hostages, as well as for the diversion of the profits to support the Contras. The report also named Marine colonel Oliver North as the main negotiator. Both the sale of weapons to Iran and the funding of the Contras were found to be in violation of Congress, particularly the Boland Amendment and the 1976 Arms Export Control Act. The report faulted President Reagan for not properly supervising his subordinates and stated that ultimate responsibility for the events were the president's alone.
Poindexter and North were found guilty of obstruction of Congress, while Defense Secretary Caspar Weinberger (1917–2006) was indicted for withholding information from the independent council. The convictions of Poindexter and North were later overturned on appeal. In 1992, following his electoral defeat to William Jefferson Clinton, President George H. W. Bush, who had served as vice president during the Iran-Contra scandal, issued presidential pardons to all who had been indicted.

IRAN-IRAQ WAR

Since its establishment in 1921, Iraq has had a precarious relationship with its eastern neighbor, Iran. The sources of contention between the two countries involved border demarcation and the desire of both states to prevent the other’s hegemonic aspirations in the Persian Gulf. However, the tensions did not result in armed conflict until Iraqi president Saddam Hussein decided to invade Iran in 1980.

Until the 1970s, both countries had been militarily and economically weak. This mutual weakness sustained a delicate balance that made open conflict undesirable to both sides. However, the rise of Iran as a regional power under Mohammad Reza Shah (1919–1980) in the 1970s undermined this balance. The Algiers Agreement of 1975 resulted in the reversal of a 1937 boundary treaty that had been preferable to Iraq. Iraq agreed to a less favorable border demarcation in exchange for Iran’s withdrawal of support from the Kurdish insurgency in northern Iraq.

The relationship between Iran and Iraq entered a new phase with the Iranian Revolution of 1979. While the revolution severely hampered the military capabilities of Iran, it greatly increased the Iraqi perception of the Iranian threat. Fearful of the destabilizing impact of the Iranian Revolution to his rule, Saddam decided to preemptively strike on September 22, 1980. The immediate goal of the Iraqi invasion was to reverse the terms of the 1975 agreement; the strategic goal was the containment of the “Islamic threat.”

Although Iraq was successful in the initial phases of the war, Iran managed to recover the Iraqi occupied territory by 1982. Yet repeated Iranian attempts to make inroads into Iraqi territory were unsuccessful, and Iraq repeatedly used chemical weapons against Iran. The war continued until 1988, when it became clear to Iran’s clerical leaders that they could not achieve any decisive breakthroughs. A cease-fire was agreed on August 20, 1988, after Iran accepted United Nations Security Council Resolution 598 of 1987. The war resulted in no major border changes.

American policies during the war were driven by the goal of containing the new Iranian regime, which had threatened American hegemony in the Middle East. Consequently, official U.S. neutrality during the war was accompanied by policies that aimed to prevent a complete Iranian victory. The U.S. Navy engaged in skirmishes with Iranian forces in the Persian Gulf, and an Iranian passenger aircraft was shot down by a U.S. cruiser on July 3, 1988. However, at the same time, the United States was covertly supplying arms to Iran to free U.S. hostages in Lebanon and to finance Nicaraguan guerrillas.

Although the “Islamic threat” was contained, the war resulted in the consolidation of the authoritarian Islamic regime in Iran. With the exception of Libya and Syria, almost all Arab countries tacitly or actively supported Iraq during the war in an effort to thwart the prospect of Iranian hegemony. In the aftermath of the war, however, Iraq emerged as a major regional power with a strong military force, a development that led to the Iraqi invasion of Kuwait on August 2, 1990.

IRANIAN REVOLUTION

A revolution is a mass movement that aims to establish a new political regime by violently transforming the existing government. The Iranian Revolution of 1978–1979 vio-
lently ended the monarchy of Shah Mohammed Reza Pahlavi (1919–1980) and replaced it with an Islamic republic, the theocracy of Ayatollah Ruhollah Khomeini (1901–1989). The shah's reign had been briefly interrupted between 1951 and 1953 with the interlude of Prime Minister Mohammed Mossadeg (1881–1967).

BACKGROUND
The shah’s rule began on September 16, 1941, and witnessed twenty-four different prime ministers heading over forty cabinets. In 1951 Iranian nationalist Mohammed Mossadeg rose to power and amassed enough support to oust the shah. He presided over the establishment of the National Front, composed of divergent forces with similar goals. Mossadeg forced oil nationalization through parliament, which provoked boycott by European powers. Shah supporters and the U.S. administration perceived him as too far to the political left. A 1953 coup restored the shah’s central authority. Alarmed over Mossadeg’s leftist backing in nationalizing the oil company, numerous clergy and the bazaaris (those who make their livelihoods in the bazaars), among some others, supported the shah in regaining power. They welcomed the U.S. Central Intelligence Agency’s (CIA) pivotal involvement in the coup.

The shah aimed to lead his country towards a great civilization, which he asserted to have pre-Islamic, Aryan roots. This insulted Iran’s devout Shi’i’s. Shi’ism, a branch of Islam that began as an opposition party, was the official state religion. Approximately ninety percent of the population was Shi’i. The shah’s monarchy was based on the constitution of 1906 and 1907. Guided by U.S. and Israeli intelligence officers, he established the National Intelligence and Security Organization (SAVAK) in 1957. It became the government’s strong arm and scrutinized allegedly suspicious organizations, such as labor unions, peasant organizations, student groups, guilds, and mosques. SAVAK’s tactics instilled pervasive fear of consequences for criticizing the regime or of disagreeing with its policies. Suspects were imprisoned, stories of torture circulated underground, and censorship laws prevailed.

The shah’s vision for Iran included a modernization program modeled after the West. In 1961 he ordered the government to implement a land law that limited the amount of land anyone could hold. Nevertheless, the Pahlavis continued to be one of the largest landowning families. The law elicited opposition predominantly from landowners, the clergy, and the resurgent National Front, culminating in riots at the University of Tehran. The peasants’ economic position generally worsened as a result of the law’s policies. Land reform also had economic consequences for religious institutions that relied on a network of exchange. In 1963 the shah inaugurated a six-point program, the White Revolution, to reshape Iran’s economic, political, and social life. Numerous Iranians saw the measures as being imposed on Iran by the United States in order to bolster the shah’s power and wealth while expanding U.S. dominance in the region. A religious uprising and a bloody counter-revolution resulted. In this context, Ruhollah Khomeini, bearing the title ayatollah, or man of God, became an emergent leader in opposition to the shah. His opposition ultimately landed Khomeini in exile in Iraq, from where he sent taped edicts and sermons to his followers.

The shah sought to develop an industrial base with an influx of foreign contractors and corporations. Some of these invested directly. In 1976 Iran was the fourth largest oil exporter in the world, and in 1977 its economy ranked fifteenth in the noncommunist world. A quantum jump in oil revenues created problems of absorbing those funds into the economic development process, resulting in dramatic increases in spending. Iran entered into a cycle of inflation, greater income inequality, corruption, and growing dependence on the West to help resolve increasing disparities. Peasants displaced to cities by land reform had to cater to thousands of Westerners for economic survival while also being confronted by the impressions Western culture had made in the cities. They found solace in the mosques, where they heard the taped sermons of Khomeini.

THE REVOLUTION HEATS UP
These massive cultural and structural changes, monitored by SAVAK, destabilized Iran’s social order. With the exception of the administration of U.S. president Jimmy Carter, which demanded the observance of human rights and restricted the availability of military equipment, the United States supported the shah’s rule. Accommodating Carter’s human rights demands, the shah relaxed his grip over the country in 1977, but the experiment failed. Instead of dialogue at the negotiating table, a series of demonstrations in the streets ensued. Khomeini continued his attacks against the shah.

On January 9, 1978 students and clergy in Qom, Iran, protested Carter’s visit to the country as well as a libelous story about Khomeini in the state press. This began a cycle of escalating violence as demonstrations became more massive and frequent. The shah declared martial law and banned demonstrations, which only provoked his opponents further. The infamous September 8 Black Friday resulted when the Iranian military responded to the public unrest and killed several hundred demonstrators in Tehran. Increasingly alienated Iranians took to the streets and hundreds were killed daily. Iran’s allies abroad distanced themselves. During the holy month of Muharram, on December 12, several million demonstrated against the shah in Tehran. The military disintegrated and the regime crumbled.
The revolution saw an eclectic alliance of secular and religious factions, including intellectuals, students, workers, peasants, bazaar merchants, trades people, and clergy. They coalesced around the Ayatollah Khomeini, who symbolized identity, stability, and social justice. In contrast to the shah, supporters perceived Khomeini as leading a simple life, refusing to compromise with foreign powers. All of the revolutionaries wanted to end the shah's rule. They differed on their vision for the type of government for Iran, but the theocratic republic prevailed. The shah was forced from the throne and left Iran on January 16, 1979, and Khomeini returned from exile on February 1.

EFFECTS
With its platform of social justice and autonomy, the Iranian Shi'i theocracy had a potentially destabilizing effect on neighboring countries with Shi'i populations. Worried over Iran's call to oppose corruption and foreign influence, particularly U.S. and Soviet policies, neighboring governments feared internal social unrest. Iran supported developing African nations, Cuba, and the Palestine Liberation Organization (PLO), among others. Iraq, with its Shi'i majority in numbers, but minority in terms of access to power, felt particularly threatened and invaded Iran in 1980. The invasion was an effort to preempt a possible Shi'i attempt to gain political power and overthrow the Sunni-controlled government of Iraq's president, Saddam Hussein. Thus began a costly and bloody eight-year war between Iran and Iraq, in which Iraq was largely supported by the United States and most Arab regimes. The war had an unanticipated consequence: Iranians with previously divergent views banded together behind their government in the face of this external threat. This development reinforced the outcome of the revolution. At the same time, as it united Iranian hard-liners and moderates even more against the United States, it influenced the nature of the future relationship between the two countries.

IRAQ-U.S. WAR
Years of tension between the United States and Iraq led in March 2003 to a direct invasion of Iraq by an American-led coalition. Iraq's Ba'th Party government, headed by Saddam Hussein (1937–2006), was quickly overthrown, but years of instability followed as a variety of Iraqi groups, and some foreigners, fought against the American occupying forces and against the new Iraqi government the United States sponsored.

In the first Gulf War, in 1991, a coalition led by the United States drove Iraqi forces out of Kuwait and destroyed much of the Iraqi military, but major coalition ground units went only a modest distance into southern Iraq; they did not attempt to enter any city.

Hussein, and most key leaders of his government and of the Ba'th Party, were Arabs belonging to the Sunni branch of Islam. Sunni Arabs made up about one-fifth of Iraq's population; they lived mostly in central and western Iraq. Another fifth were Kurds, who lived overwhelmingly in the north. Arabs belonging to the Shiite branch of Islam made up a majority of the population; they were especially strong in the south. Most of the Kurds were Sunni, but when people spoke of “the Sunnis” in Iraq, they almost always meant just the Sunni Arabs, not the Kurds.

Immediately after the 1991 war, there were revolts by both Shi'ite Arabs in the south and Kurds in the north. The government put down the Shiite rebellion with great brutality, but international intervention helped the Kurds achieve de facto autonomy in a large region of northern Iraq, called Kurdistan.

Iraq grudgingly accepted United Nations Security Council resolutions under which it was to eliminate, under international supervision, all nuclear, chemical, and biological weapons (“weapons of mass destruction” or WMDs). Hussein believed at first that he could conceal Iraq's extensive WMD programs and stockpiles from UN inspectors, but the inspectors proved more effective than he had expected. He then disposed of most of his prohibited weapons and programs, keeping no more than he had expected. He then disposed of most of his prohibited weapons and programs, keeping no more than he could reasonably hope to conceal from the inspectors.

Years of cat-and-mouse games followed. Late in 1998 the United States and Britain launched strikes using aircraft and cruise missiles to punish Hussein for his refusal to cooperate with the inspection process. The inspectors withdrew from Iraq before these strikes, and did not return afterward.

Iraq remained under severe economic sanctions, originally imposed late in 1990 after the Iraqi invasion of Kuwait. The effect of these was moderated only somewhat by the “oil-for-food” program after 1996. The Iraqi econ-
omedy remained crippled, and the Iraqi armed forces remained far below their 1990 strength for lack of funding. U.S. aircraft patrolled large “no-fly zones” where the Iraqis were forbidden to operate military aircraft. The patrol aircraft frequently bombed antiaircraft guns, surface-to-air missiles, and radars when the Iraqis fired on aircraft or seemed about to do so.

**TOWARD A SECOND WAR:**

*2001–2003*

After the Afghanistan-based terrorist organization Al-Qaeda attacked the United States on September 11, 2001, President George W. Bush quickly began thinking of invading Iraq. Senior administration officials believed that significant links existed between the Iraqi government and Al-Qaeda. In June 2002 they increased the frequency of U.S. air strikes in southern Iraq. These continued to be officially explained as responses to attacks and threats against aircraft patrolling the no-fly zones. But, in fact, the United States was systematically destroying Iraqi air-defense systems.

The U.S. Congress authorized the use of force against Iraq on October 10, 2002, but the UN Security Council was reluctant to go so far. Security Council Resolution 1441, passed on November 8, offered Iraq “a final opportunity to comply with its disarmament obligations,” with a reminder that the Security Council “has repeatedly warned Iraq that it will face serious consequences as a result of its continued violations of its obligations.” The United States expected, after a short interval, to obtain a second resolution stating that Iraq had missed its final opportunity, and authorizing force. But Iraq allowed the UN weapons inspectors to return before the end of 2002, and gave them cooperation that was, while not perfect, far better than at any time in the 1990s. In early 2003 the United States was arguing, with evidence that later turned out to have been mostly inaccurate, that Iraq’s WMD programs and stockpiles were so large and diversified as to constitute a major threat, justifying military action. But it was difficult to reconcile these American claims with the failure of UN inspectors to find any WMDs, despite searching in the places where American officials told them to search.

The U.S. government responded by attacking the credibility of the inspectors. But French Foreign Minister Dominique de Villepin and his allies, who argued that there was no immediate need for war, drew increasing support from the members of the Security Council. President Bush decided to go to war without UN authorization, as head of a “coalition of the willing.”

**THE INVASION OF IRAQ:**

*MARCH–APRIL 2003*

Early on March 20, 2003, the United States tried to kill Saddam Hussein and his two sons using aircraft and Tomahawk cruise missiles. The ground invasion of Iraq, coming from Kuwait, began a few hours later. The number of troops involved was surprisingly small. American leaders were so confident of Iraq’s weakness that, for an invasion aimed at taking the whole country, they used a force far smaller than the one they had sent in 1991 to accomplish much more limited goals.

A primarily British force occupied the extreme southeast, around the city of Basra. American troops took the main body of Iraq. Marine units, on the right wing, crossed the Euphrates River at Nasiriyah; the heaviest American losses of the campaign were in that city. Most of the Marines proceeded north, crossed the Tigris River, and then turned west toward the capital, Baghdad. Army units, on the left wing, went west across the deserts south of the Euphrates until they were south or even a little southwest of Baghdad, then turned north and finally came at Baghdad from the southwest.

Iraqi air defenses had been so weakened by months of American air strikes that U.S. helicopter gunships and fixed-wing aircraft were able to operate in comparative safety in large areas of Iraq. They devastated Iraqi military units in the path of the American ground forces, especially the larger units with heavier weapons. What remained of the Iraqi forces were no match for American ground forces. And the Americans moved so fast that the Iraqis had little opportunity to draw lessons from the defeat of one unit that could enable another to do better.

The speed with which the Americans advanced would have made them vulnerable to ambushes, and attacks on their supply lines, by competent and innovative enemy forces. They encountered few such forces. The Iraqi units that were willing to fight—that did not just fade away—mostly placed themselves unimaginatively in the path of the American juggernaut, and were crushed by it. The first unpleasant surprise for the Americans was a paramilitary organization, the Fedayeen Saddam. But the surprise was that the Fedayeen Saddam fought at all. They did not fight with great skill, they did not have heavy weapons, and they did not inflict heavy casualties on the Americans. Another surprise was more ominous. On March 29 a suicide bomber driving a taxi killed four U.S. troops at a checkpoint. Another suicide bomber killed three Americans on April 3.

Small groups of American forces went into northern Iraq by air, seizing some positions themselves and helping Kurdish forces, the peshmerga, to seize others. The United States had hoped to send in a much larger force through Turkey, but the Turks had refused permission.
American bombing of the Iraqi air-defense system before the nominal opening of the war had been effective, and the tactical air strikes that supported the ground invasion were very successful. American strategic bombing during the war was less so. The “shock and awe” bombing of conspicuous government buildings and palaces in central Baghdad, on March 21, did not have the hoped-for psychological effect.

The American forces went more than half the distance from Kuwait to Baghdad in a week, paused for a few days to allow supplies to catch up with the front of the advance and to clear Iraqi forces away from their supply lines, and then resumed their advance. U.S. Army troops had full control of Baghdad’s main airport, west of the city, by April 5. On that day, a task force of tanks and other tracked vehicles made an armed reconnaissance patrol, a “thunder run,” going deep into Baghdad from the south and then radioing to the west. One American was killed, but American forces killed an estimated eight hundred to one thousand Iraqi soldiers. Two days later the same task force and two others made a second thunder run. This time they went to the heart of the city, occupying, among other sites, two of Hussein’s palaces beside the Tigris, and remained there. The Iraqis were unable to dislodge them on April 7 and 8, and meanwhile other Army units were entering the city from the northwest. U.S. Marines were coming from the southeast. During the night of April 8 to 9, Iraqi leaders, recognizing that they had lost the struggle for Baghdad, went into hiding. Their government ceased to function as a government, though some of their soldiers continued to resist the Americans.

Looting began in parts of Baghdad on April 7. It reached disastrous levels on April 9. There were not nearly enough American troops to restore order, and they did not at first even make much of an attempt; few thought of the maintenance of order as their responsibility.

**RECONSTRUCTION AND RESISTANCE**

The United States had done little to prepare for the occupation of Iraq. Apparently it was believed that once Saddam Hussein was gone, a new government, with exiled leaders such as the secular Shiite Ahmad Chalabi playing key roles, could be created with little further American effort. When this did not happen, Paul Bremer was sent in May 2003 to head a new body, the Coalition Provisional Authority, which ruled Iraq until mid-2004. An “Iraqi Governing Council” was established in July 2003 but was not given much authority.

An insurgency made up primarily of Sunni Arabs emerged gradually out of the background of general lawlessness that followed the war. Its diverse elements often cooperated, but had no overall command. First, there were the surviving elements of the Ba’th Party. When the government collapsed in April 2003, leaders and officers going into hiding took with them considerable funds, some of which they used to finance the insurgency. The Americans at first overestimated the importance of the Ba’th leaders, and hoped that the capture of Hussein in December 2003 would seriously weaken the insurgency, but there was not much effect. (Hussein’s execution in December 2006 seemed, if anything, to inflame the insurgency further.)

Groups rooted in local communities and tribes formed the great mass of the insurgency. Many felt a nationalist hostility toward foreign occupiers. Many resented the way the Americans had reduced the power of the Sunni Arabs, traditionally the dominant force in Iraq, by empowering the Shiite majority and the Kurds. Many were angry with the number of Iraqis the Americans had killed, about the way troops searched Iraqi homes at night, looking for weapons and hauling off suspects in handcuffs and hoods, and so forth.

Finally, there were foreign fighters from many countries. The most important of these were very similar to Al-Qaeda and eventually began calling themselves “Al-Qaeda in Mesopotamia.” They were led by a Jordanian, Abu Musab al-Zarqawi, until his death in June 2006. They thought of Iraq as one front in a broader struggle directed both against the United States and against corrupt secular governments in the Muslim world. They are believed to have been responsible for most of the spectacular suicide bombings in Iraq, killing large numbers of people, including many Shiite civilians, and trying to trigger a civil war of Sunnis against Shiites.

The coalition headed by the United States had a substantial number of British troops and smaller numbers of troops from other nations, but these were overwhelmingly in areas of southern Iraq that were predominantly Shiite. It was the Americans who faced the Sunni Arab insurgency.

The violence had become a major problem by August 2003, and it grew thereafter. By early 2004 numerous towns were under insurgent control. In April, when the United States assaulted Fallujah, west of Baghdad, it became apparent that taking Fallujah would require so much firepower as to destroy much of the city. The Americans backed off, and Fallujah remained under insurgent control until it was finally taken in a bloody battle that indeed destroyed much of the city in November 2004.

At times, the coalition faced a dangerous widening of the insurgency into the Shiite community. A radical young Shiite cleric, Moqtada al-Sadr, wanted Iraq to have a religiously based government similar to that of Iran. His militia, the Mahdi (Mehdi) Army, clashed with American forces on a serious scale in April 2004, and again in August.
On June 28, 2004, the United States officially granted sovereignty to an Iraqi government headed by Prime Minister Ayad Allawi, a secular Shiite. In January 2005 elections were held for a national assembly. An alliance of religiously oriented Shiites, presided over but not openly led by Ayatollah Ali al-Sistani, the most respected religious leader in Iraq, won a majority of the seats. A constitution was then written, and an election under the new constitution was held in December 2005. Many more Sunni Arabs voted in this election than had voted in January. It was hoped that this development would lead many of those who had supported the insurgency to shift their efforts toward participation in peaceful political processes. But this did not quickly occur.

In the second half of 2004, the United States significantly expanded its efforts to train Iraqi military and security forces. By the second half of 2005, Iraqi forces were having a clear and substantial impact, establishing, for example, a reasonable level of security on the notorious highway linking the city of Baghdad with its airport. But there was increasing concern about the extent to which some elements of the security forces, especially the police, were being infiltrated by and becoming tools of the militias of Sadr and other religiously oriented Shiite leaders.

For a long time, the Shiites showed remarkable restraint, not retaliating indiscriminately for Sunni insurgents’ murders of Shiite civilians. But in February 2006 insurgents blew up the Golden Mosque in Samarra, one of the holiest Shiite shrines in Iraq, and the Shiites exploded in rage. Soon Shiite “death squads” were abducting, torturing, and murdering Sunnis by the thousands, and Sunnis were doing the same to Shiites in a cycle of revenge killings, mainly in Baghdad and nearby cities, that produced higher death tolls than the ongoing struggle pitting the insurgency against coalition and government forces. Militants on each side carried out ethnic cleansing, driving members of the other group out of mixed neighborhoods. The United States blamed Shiite militias, especially the Mahdi Army, for the worst of the violence. But Prime Minister Nuri al-Maliki was politically allied with Moqtada al-Sadr and other religiously oriented Shiite leaders; he often resisted American efforts to crack down on the militias.

U.S. Secretary of Defense Donald Rumsfeld was determined to use as few American military personnel as possible in the occupation of Iraq, and he long downplayed the magnitude of the problems there. Critics argued that the American force in Iraq was too small to accomplish its mission. But as the violence escalated, political support for the war effort declined in the United States. Critics of government policy increasingly spoke of setting a timetable for withdrawal of the forces the United States already had in Iraq, rather than sending more.

Rumsfeld resigned at the end of 2006, and top American officials spoke more openly than ever before about the need for a change of policy. In January 2007 President Bush announced that Prime Minister al-Maliki had committed himself to a real crackdown on violent militias, regardless of sect. Bush also announced that he was sending more than 21,000 additional American troops to Iraq, most of them to Baghdad, to support Iraqi government efforts to restore order. Few in the American public or the Congress had much faith that this new effort would succeed, though as of spring 2007 violence in and around Baghdad decreased significantly.

IRISH REPUBLICAN ARMY

The term Irish Republican Army was first used during the Fenian raids in Canada during the 1860s. Today the term is used in concert with the outbreaks of violence throughout Ireland, and especially in Northern Ireland, called the Troubles. The Irish Republican Army has a much longer
history than that begun in the late 1960s and early 1970s, having been instrumental in the Easter Uprising in 1916. The *Troubles* refers to the sectarian conflict in Ireland (especially Northern Ireland) that began in the late 1960s.

The immediate postfamine years in Ireland were a period of escalating unrest between the Irish and their English occupiers. In 1916 the conflicts came to a head when a group of charismatic Irish began a revolt in Dublin. The focal point of the revolt was the General Post Office, now a shrine to their efforts, but the entire city, especially the area in and around O’Connell Street and Parnell Square, was involved in the violent armed conflict. In the end, the leaders of the revolt were arrested, put in Kilmainham Gaol, and many were executed. In the aftermath of the uprising and their executions, Michael Collins (1890–1922) and others organized guerrilla forces against the English Black and Tans. These forces became known as the Irish Volunteers.

In 1919 the Dáil Éireann or First Dáil (the government of Ireland) recognized the Irish Volunteers as the Irish Republican Army (IRA), and they in turn fought the Irish War of Independence from 1919 to 1921 against the English. At the signing of the Anglo-Irish Treaty in 1921, the IRA split into pro-treaty forces (which became known as the Old IRA, government forces, or regulars) and antitreaty forces (Republicans or irregulars). The antitreaty forces continued to use the name Irish Republican Army. In 1922 the two sides entered into the Irish Civil War, with the regulars led by Michael Collins on the side of the new Irish Free State, which still recognized England, and the Republicans led by Liam Lynch (1893–1923) refusing to recognize the new state or the partitioning of Northern Ireland. Collins was later assassinated by IRA members for his participation in the Civil War and support of the Free State government.

Éamon de Valera (1882–1975), a member of the antitreaty group Sinn Féin, eventually came to power as leader of the Fianna Fáil Party, currently the largest political party in Ireland. The IRA remained active in the Republic until the 1960s, when it split again to become the Official IRA (OIRA) and the Provisional IRA (PIRA). The Provisionals were most active in Northern Ireland and split with the Official IRA due to what they recognized as the OIRA’s lack of protection for nationalist communities in the North. This split came in 1969 as violence between sectarian communities and Republican and Unionist groups began to escalate. This is often recognized as a conflict between Catholics and Protestants in the North, but the underlying reasons remain tension between Unionists (those who support English rule) and Republicans (those who support unity with the Republic of Ireland and devolution from England).

Bloody Sunday, a violent clash between protesters and British and Northern Irish troops in Derry in 1972, was a flashpoint in the sectarian conflicts. Troops opened fire upon the crowd of protesters killing thirteen, all of whom were unarmed. There are conflicting reports from those present that suggest either a gun was fired from the protesters’ side toward the troops or that the troops were commanded to fire on the agitated crowd. In the days and months that followed, extreme violence in the form of shootings, bombings, murders, and arson engulfed the North. The PIRA carried out many of the killings and are suspected to be the perpetrators of specific acts of violence carried out against the Royal Ulster Constabulary (RUC) and the British army, among them the bombings of police stations and barracks and the targeting of pubs frequented by the RUC and the army. They are also accused of a number of attacks in Dublin and throughout the United Kingdom. In over thirty years of violence in Northern Ireland, more than three thousand people have died as a result of the conflict.

Since the mid-1990s, a process of political devolution has been under way in Northern Ireland. The peace process, as it is known, has been opposed by many, including the Real IRA, a splinter group of the PIRA that broke ranks in 1997. The Real IRA, considered to be a paramilitary group, has held out against the decommissioning of weapons as proposed in the Hume-Adams report. In 1993 the Hume-Adams initiative agreed to by John Hume, leader of the SDLP (the North’s nationalist party) and Gerry Adams was a directive to begin an IRA cease-fire and to include Sinn Féin in the peace talks. This in turn led to a series of cease-fires and began the peace process. Sinn Féin, led by Gerry Adams, entered the Dáil Éireann and now participates in the political decision-making process.

IRON CURTAIN

The term iron curtain was coined by the British author and suffragette Ethel Snowden in her book *Through Bolshevik Russia* (1920). In her very early and negative critique of the Bolshevik form of communism, this British feminist referred to the iron curtain simply as the contemporary geographical border of Bolshevik Russia in 1919 ("We were behind the 'iron curtain' at last"). At the end of the Nazi regime in Germany the minister of propaganda, Joseph Goebbels, used the term in a journal article and several times in his private diary in February 1945, and the minister of finance, Lutz Graf Schwerin von Krosigk, used it in a radio broadcast on May 2, 1945. Both Nazi leaders argued that the Soviet Army is occupying one country after the other, lowering an iron curtain immediately afterward on these occupied countries in order to commit war crimes, without being observed and controlled by the outside world. During the last months of the Third Reich, both ministers regarded the iron curtain as a moving part of the ongoing occupation process by Soviet troops within the territorial scope of the Yalta agreements from 1943. This analogy with an iron curtain in a theater (Goebbels was in charge of German theaters and culture) in this usage of the notion refers to the fact that events behind the theater curtain are not visible by the audience and somehow cut off from outside observation. The British prime minister Winston S. Churchill used the term in a diplomatic telegram to President Harry S. Truman in May 1945, and in a public speech in the British Parliament on August 16, 1945, but the term was not popularized until the following year, with Churchill's speech at Westminster College in Fulton, Missouri, on March 5, 1946:

> From Stettin in the Baltic to Trieste in the Adriatic an iron curtain has descended across the Continent. Behind that line lie all the capitals of the ancient states of Central and Eastern Europe, Warsaw, Berlin, Prague, Vienna, Budapest, Belgrade, Bucharest and Sofia; all these famous cities and the populations around them lie in what I must call the Soviet sphere, all are subject, in one form or another, not only to Soviet influence but also to a very high and in some cases increasing measure of control from Moscow. (Cannadine 1990, pp. 303–304)

The iron curtain refers to the boundary that divided Europe politically and militarily from the end of World War II until the end of the cold war. Geographically, the borderline ran from Estonia in the north to Yugoslavia in the south. Churchill's famous 1946 address, which is sometimes referred to as the "Iron Curtain Speech," is regarded as marking the commencement of the cold war between the democratic Western world and the Communist Eastern bloc with the Soviet Union as its political center. Between 1946 and 1989, the existence of this symbolic boundary forced many Central and East European countries to join the Communist bloc under the control of the Soviet Union. These countries—Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, Romania, and (until the 1960s) Albania—were labeled "Iron Curtain countries."

The iron curtain was manned and defended militarily against the West by the Warsaw Pact, which combined the Soviet Red Army and troops from the new Communist one-party states after the end of World War II. It also served as a wall to prevent citizens of Eastern bloc countries from migrating west. In Berlin, the section of the iron curtain dividing West from East Germany took the form of the Berlin Wall, a long concrete wall separating Berlin into democratic and Communist parts; many East Germans lost their lives trying to escape over the wall to the West. In other areas, the iron curtain was constructed of nearly impenetrable steel fencing, creating a long and narrow strip of no-man’s-land of untouched wildlife.

The iron curtain was finally lifted on June 27, 1989, at the border between Austria and Hungary by the foreign ministers Gyula Horn (Hungary) and Alois Mock (Austria), forty-three years after Churchill's historic speech. This first crack in the long border between the free world and the Communist world was the beginning of the final collapse of communism in November and December 1989, and the first sign of the fall of the Soviet Union in 1991. The fall of the iron curtain coincided with the end of the cold war, signifying the end of a crucial and dramatic period of European and world history.

IROQUOIS
The Iroquois were a Native North American confederacy of five nations whose aboriginal territory included much of upstate New York. The Iroquois thought of this territory as a longhouse, a rectangular multifamily dwelling with a door at each end and a series of hearths in the aisle that ran the length of the dwelling. Each of the five Iroquois nations occupied one of the five fireplaces in this metaphorical longhouse. From east to west these were the Mohawk, the Oneida, the Onondaga, the Cayuga, and the Seneca. As the western-most nation in the Iroquois longhouse, the Senecas were considered the “Doorkeepers of the Confederacy” and the Mohawks are often styled the “Keepers of the Eastern Door.” Iroquois refer to themselves as Haudenosaunee (with variant spellings) meaning, roughly, “people of the longhouse,” a designation many contemporary Haudenosaunee prefer. Iroquois was the name utilized by the French; the English usually referred to the confederacy as the Five (later, Six) Nations.

At the time of contact with Europeans the Iroquois lived in large villages consisting of elm-bark longhouses, each housing a number of families. Surrounding the village were fields in which the women planted the “three sisters”—corn, beans, and squash. These crops were the staples of Iroquois diet.

Each of the Iroquois nations was divided into exogamous matrilineal clans. The Wolf, Bear, and Turtle clans were found in all five nations; five or six additional clans were found among the Onondagas, Cayugas, and Senecas. The clans were further divided into matrilinages, each headed by a senior female, the lineage matron. Some of these lineage matrons enjoyed considerable political power. The Iroquois Confederacy Council consisted of fifty positions, each hereditary within a matrilinage. The lineage matron appointed a male member of her matrilinage to that position and had the right to depose him if he proved negligent or incompetent in that role.

Dean Snow estimated the Iroquois population as almost 22,000 in 1630, prior to their first experience of smallpox (Snow 1994, p. 110). Diseases introduced to North America from Europe took a terrible toll in Iroquoia, but these population losses were to some degree offset by the Iroquois practice of adopting war captives and incorporating refugee populations. One refugee group, the Tuscarora, arrived in the 1720s, and after their arrival the confederacy was often known as the Six Nations.

Initially the Iroquois established a strong trading relationship with the Dutch colony of New Netherland. The Iroquois quickly adopted elements of European culture such as brass kettles and steel axes and knives. These economic and political ties continued after the English replaced the Dutch as governors of the colony, having renamed it New York.

Occupying a highly strategic position between the English colonies on the Atlantic Coast and the French in Canada, the Iroquois usually maintained neutrality between the two colonial powers. On occasion Mohawks took the field as allies to the British whereas the Senecas, close to the French trading post at Niagara, sometimes fought beside the French. There were several Mohawk colonies on the St. Lawrence River established by converts to Catholicism who were persuaded by their Jesuit priests to migrate to a locale remote from English influences. These people, from the founding of their communities in the 1670s, consistently fought as allies to the French.

By the outbreak of the American Revolution the Iroquois had largely abandoned the multifamily bark longhouses and were living in smaller houses, often log cabins. The Mohawks had converted to the Church of England. The Oneida were heavily influenced by the New England missionary Samuel Kirkland (1741–1808). Those nations farther to the west were not yet Christian, but their towns closely resembled those of the non-Indian inhabitants of the frontier.

The American Revolution divided the Iroquois Confederacy. The Oneidas and Tuscaroras aided the supporters of the Continental Congress; Mohawks, Cayugas, and Senecas (and later the Onondagas) fought as allies to the British. The treaty that ended that conflict in 1783 made no provisions for the Indian allies of the Crown, and Britain surrendered all interests in the Iroquois homeland south of Lake Ontario. Many Iroquois moved north of the new American border to lands secured for them by Quebec governor Frederick Haldimand. These lands included the Tyendinaga Mohawk Reserve (or Territory) on the Bay of Quinte and the Six Nations Reserve on the Grand River, both in what is now Ontario. The latter was settled predominantly by Mohawks, Cayugas, and Onondagas. Most of the Senecas remained in New York State, and a series of treaties (Fort Stanwix [1784], Canandaigua [1794], and Big Tree [1797]) established several reservations, of which Allegany, Cattaraugus, Oil Spring, and Tonawanda remain in Seneca hands. The
Onondaga Nation retains territory near Syracuse, New York, but Cayuga and Oneida lands in New York were purchased through treaties of questionable legality with the State of New York. The larger portion of the Oneidas migrated to lands secured in Wisconsin and Ontario early in the nineteenth century.

In 1799 a Seneca, Handsome Lake (1735–1815), experienced a vision that led him to preach a message of both nativism and reform that established the contemporary practice of traditional Iroquois (or Longhouse) religion. Anthony F. C. Wallace's ethnohistorical analysis of these events formed the basis of anthropological understanding of revitalization movements (Wallace 1970).

In the 1840s Lewis H. Morgan pursued personal contacts, particularly through a bilingual Seneca youth, Ely S. Parker, among the Tonawanda Senecas to compile what has been touted as the first ethnographic monograph describing a Native North American culture (Morgan 1851).

Any estimate of current Iroquois population is subject to error, but a compilation of numbers of those formally enrolled in various Iroquois communities between 1990 and 2000 states that 16,829 are enrolled in New York Iroquois communities, 42,857 belong to communities in Ontario, 10,831 are enrolled in Quebec Iroquois bands, 11,000 belong to the Wisconsin Oneida community, and 2,460 belong to a Seneca-Cayuga group that resides in Oklahoma (Lex and Abler 2004, p. 744).

Some Iroquois communities have pursued land claims for nearly two centuries (see Vecsey and Starna 1988), seeking the return or compensation for lands felt to be fraudulently taken. These claims have led to violent clashes with authorities, as at Ganienkeh in northern New York in the 1970s and at Kanesatake outside Montreal in 1990. Legalized gambling and other economic activities have also deeply divided many communities, creating internal conflicts that have led in some cases to violence, arson, and even deaths.

IRREDENTISM

SEE Nationalism and Nationality.

IRRIGATION

Irrigation refers to techniques for augmenting the moisture content of soil to grow crops. These techniques have played an important role in intensifying agriculture, increasing production, and improving the productivity of land and labor. Early civilizations in China, Egypt, Mesopotamia, Peru, and India relied on them to support large and complex populations. One of the earliest and most successful large-scale hydraulic works was the Dujiangyan irrigation project built in the third century BCE in southwest China’s Sichuan Province. The project was designed to simultaneously solve the problem of the incessant flooding of the Minjiang River, a tributary of the Yangtze River, in the summer, and provide water during the winter when it was beset with drought. Working without a dam, the river was divided by a long bank in the middle, with the inner river serving as a channel for delivering water for irrigation and the outer river used as a floodway. This enabled the delivery of water during the dry season and the return of excess water during the winter to the mainstream of the Minjiang River. A weir made of bamboo cages filled with stones balanced the channel’s inflow. The project fed a grid of irrigation canals watering 160,000 hectares of arable land in the Chengdu Plain.

Many ancient large-scale irrigation systems were accompanied by elaborate, complex, social organization. Descriptions of these systems in the nineteenth century intrigued the social theorists Karl Marx (1818–1883) and Max Weber (1864–1920). Marx’s idea of the Asiatic mode of production, based largely on irrigation-based societies in China, included state control and collection of rents, a despotic political system, and societal organization obtained through religion, rather than economics and exchange. Village life, rather than cities, circumscribed the social spheres of people. Weber, in contrast, drew atten-
tion to the peculiar “hydraulic-bureaucratic official-state” in China and India. Although flawed due to limits in the data then available, these constructs were quite influential in the subsequent development of social theory.

Karl Wittfogel, inspired by the writings of Weber, revisited the materials and proposed in Oriental Despotism (1957) that large-scale waterworks required centralized direction, bureaucratic organization, and disciplined armies. He distinguished such “hydraulic societies” from smaller-scale “hydroagricultural societies” relying on less provident water sources in regions where geographical features hydraulically compartmentalized the countryside. Wittfogel’s hydraulic society thesis generated various criticisms, of which the most telling were examples of locally controlled and managed irrigation in societies where irrigation authority was formally centralized. More recently, Donald Worster in Rivers of Empire (1985) reinvigorated the discussion of large-scale irrigation, arguing that Wittfogel’s hydraulic societies take a somewhat different form in the modern world. In his analysis of river-based irrigation in the western United States he finds parallels between the archaic centralized regimes of ancient hydraulic societies and the centralized state agencies of the Bureau of Reclamation and the Army Corps of Engineers.

IRRIGATION TECHNIQUES
The motivation for irrigation stems from the difficulties of farming in arid and semiarid areas of the world beset with insufficient or unreliable precipitation. Where precipitation is insufficient, irrigation may be the only way farmers can supply moisture for growing crops. In areas with sufficient, but otherwise unreliable, precipitation, it can provide insurance against crop failure. And in lands with adequate moisture, irrigation can be used to grow water-intensive subsistence crops such as rice, or high-value market crops such as sugar beets or beans.

Irrigators commonly draw on gravity to move surface water from a source through channels and furrows to fields and to store water in reservoirs and cisterns. Techniques to move surface water run the gamut from simple and unsophisticated counterbalanced poles mounted with buckets to complex, labor-intensive feats of engineering such as large-scale dams and canal systems. Surface-water irrigation often works in concert with the control and manipulation of floodwater. In one frequent form, as soon as the flood in a perennial river reaches a sufficient level, inundation canals start to flow and water is led over fields. In another, recession irrigation, a rising perennial river overflows its banks and inundates the plains alongside the river. Crops are grown on the rising or receding flow or on the residual moisture.

In spate irrigation, found throughout semiarid environments of the Middle East, North Africa, East Africa, West Asia, and parts of Latin America, seasonal water is used as a source. Seasonal floods are contained in mountain catchments or diverted from riverbeds and spread over large areas. Seasonal floodwater may last only a few hours or a few days, and sophisticated local knowledge is required to organize and manage the accumulation and distribution of the floodwater. Spate irrigation is associated with low returns to labor, great variability in productivity between good and bad years, and a high degree of social organization. Its uncertainty restricts its appeal to only the very poorest.

In areas with high water tables or surface depressions, human or animal energy has been used to raise groundwater for irrigation. Gravity usually has only limited potential in this regard. One exception is the complex “horizontal wells” that tapped subterranean aquifers through filtration galleries in the ancient Middle East (qanats), and the Andes (puquios). In the nineteenth century pumps driven initially by steam and later by electricity and gasoline or diesel, were adopted to irrigate with groundwater from shallow aquifers and deep groundwater basins. The availability of small, portable, inexpensive, submersible pumps in the late twentieth century expanded groundwater irrigation dramatically. In groundwater-rich spate-irrigated areas, hydraulic infrastructure has been neglected and land use intensified through perennial cropping.

The adoption of industrial irrigation altered significantly the scale, impact, and productivity of agriculture, and its reliance on inanimate mechanical converters of energy, especially fossil fuels. Irrigation played a key role in the Green Revolution of the 1960s, helping to ensure the high yields of “miracle seeds.” It remains instrumental in realizing the potential of genetic engineering and precision agriculture, the application of space-age technologies to tailor soil and crop management to local conditions. Two techniques now in widespread use include drip irrigation, relying on emitters to release carefully calibrated amounts of water, and sprinkler irrigation, with relatively permanent or portable sprinkler systems.

Despite new and more efficient irrigation technologies, today’s demands for water produced by the Green Revolution, population growth, urbanization, and industrialization outstrip supply. Scarcity of water provokes conflicts in many areas of the world; they are endemic in the Middle East over access to the water of the Euphrates, Jordan, and Nile Rivers. At the heart of the Arab-Israeli conflict is the allocation to Israel, Jordan, the Palestinian Territories, and Syria of the water of the Jordan River, its tributaries, coastal rivers, and two aquifer systems.

SUCCESSES AND FAILURES
Although many regions in China, Egypt, Mesopotamia, and India have enjoyed continuous and sustainable irriga-
tion for centuries, it has not always been an unmitigated success. Archaeological and historical research has uncovered significant evidence of cases of agrarian collapse due to environmental degradation and mismanagement. Poorly managed surface-water irrigation can lead to the excessive buildup of salts, exacerbated by shallow soils, water with relatively high salt content, aridity, and high water tables. For example, the Aral Sea, located in inland Central Asia, has been shrinking since the 1960s as the U.S.S.R. diverted the rivers that feed it for irrigation.

Often, inadequate drainage is at the root of the irrigation failures. Drainage does not always have to be a problem, however. Some societies have devised techniques for draining heavily waterlogged soils to levels sufficient to support intensive agriculture. Raised-bed agriculture in Lake Titicaca of southern Peru and Bolivia achieved levels of productivity comparable to irrigated land.

In the industrial era, irrigation has increased the risks of ground- and surface-water pollution from the intensive use of pesticides and nitrate fertilizers. Groundwater extraction poses an additional problem; it is much more difficult to regulate than surface-water irrigation and in many regions of the world, overpumping has contributed to the drying up of aquifers and groundwater basins.

ISLAM, SHIA AND SUNNI

Islam was born in the Arabian Peninsula in the seventh century CE, a time when the peninsula was populated by nomadic tribes, as well as settled agriculturalists and merchants. There was no central authority beyond a scattering of tribal leaders, most of them devoted to polytheistic religions.

The Prophet Muhammad was born around 570 CE, in Mecca. His family came from a poor branch (the Banu Hashim) of the leading Meccan tribe (the Quraysh). His father died before he was born and his mother died when he was a child; he was brought up by his grandfather and uncle. As a young man, Muhammad worked as the business manager of a wealthy widow named Khadijah (d. 619). He was dubbed “the trustworthy” for his business dealings and was thoroughly respected. He married Khadijah, who was his senior, when he was in his twenties. They had four daughters who married into eminent families. Little more is known about his early life before his “call” at age forty.

Like other young men in Mecca, Muhammad made solitary retreats into the nearby mountains. He was known to have become contemplative about leading a pure and honest life. On one of these occasions, he had a vision in which the angel Gabriel commanded him to recite God’s message which is now encapsulated in the Qu’ran, Sura 96, verses 1–5. According to the hadith, a collection of the Prophet’s sayings and actions, Muhammad was terrified by his vision. He is supposed to have wondered whether he was going mad, and he was physically affected by these thoughts, which he knew were not his own; this manifestation has been compared to an epileptic seizure.

Muhammad was reassured by his early supporters, including his wife, his cousin Ali ibn Abi Talib (599–661), and his close friends Abu Bakr (c. 573–634) and Uthman ibn Affan (d. 656), that he was not losing his mind. In 613 Muhammad began preaching in the streets of Mecca. His monotheistic message offended leading members of the dominant Quraysh, and he was scorned, derided, and attacked. One of his persecutors, Umar ibn al-Khattab (c. 586–644), later became a convert.

In 619 Muhammad’s wife and uncle died, and his position in Mecca became precarious. He began to look for support outside of Mecca, and was encouraged by exchanges with people from Medina (about 250 miles north of Mecca), a town with a population of émigré Jews. In 622 he moved to Medina in the so-called hijrah (migration), and, around this time, he gave his movement a political identity, formulating the ideal of a community of religious believers, known as the ummah.
In Medina, Muhammad came into contact with Christians as well as Jews and soon became a leader in the community. In 624 he began to ambush the caravans of Meccan traders in an attempt to economically and psychologically undermine the prestige of the Quraysh clan. The Meccans responded by sending an army against Muhammad and his followers, who, though seriously outnumbered, were victorious. Muhammad led an expedition into Syria, and his military prowess won him the support of Bedouin tribesmen. In 627 the Quraysh again were unsuccessful in their attempts to suppress Muhammad and his followers. In 630 Muhammad returned to Mecca as the leader of a united Arabian Peninsula. He died in 632.

After Muhammad’s death, his followers expanded throughout the Mediterranean basin and into the east. In the west, their expansion was checked by the Frankish ruler Charles Martel (c. 688–741) at the Battle of Tours in 732.

Muhammad’s death precipitated a crisis among his followers. The community was in danger of crumbling, and it was only through the vigorous efforts of his successor, Abu Bakr, that it survived. Abu Bakr kept the Arabs unified by pursuing an expansionist policy, invading Syria and Iraq. When Abu Bakr died, he was succeeded by Umar, who continued the expansion, taking Egypt and Syria, and overthrowing the Persian Empire. Umar’s conquests were culturally important in that they brought a refined civilization within the Muslim orbit.

When Umar died in 644, the succession was contested. The two main candidates were Uthman and Ali. The electors chose Uthman. Uthman’s reign began with an initial period of calm followed by corruption and lawlessness. He was asked to abdicate his position by the son of the first caliph Muhammad Abi Bakr, who reportedly was part of a group of men from Egypt who seized Uthman’s house and murdered him. After Uthman’s death, Ali took control, but a civil war broke out between him and Uthman’s cousin, Muawiya ibn Abu Sufyan (d. 680), the governor of Syria. In 661 Ali was murdered by Ibn Muljam of the Kharijites (secessionists), one of the earliest sects of Islam that contested the validity of the caliphate, and the line of “right-guided” caliphs (community leaders) ended. Muawiya inaugurated a new dynasty (the Umayyad caliphate), centered in Damascus.

The civil war precipitated the first split in Islam. A minority group, known as Shiites, became differentiated from the majority (later to be known as Sunnis) in their belief that the descendants of Ali had a special claim to authority. Many Shiites assert that they are linked by blood to the Prophet through a series of holy men. In subsequent centuries, further splits developed within Shia Islam.

The Umayyads continued the holy war, spreading into North Africa, Spain, and France. Their success resulted from the weakness of the Byzantine Empire and the Latin West, the bureaucratic skills of the Umayyad caliphs, and the fact that the Germanic Goths and Vandals had trouble adapting to a settled way of life. In the 740s the Umayyad dynasty gave way to the Abbasid line, and the center of Islam moved from Damascus to Baghdad.

THE BASIC RELIGIOUS TENETS

Muslims of all sects share several basic principles. At the center are two main doctrines: (1) there is one God; and (2) the righteous are required to submit to God. Etymologically, Islam means “submission to God” and Muslim means “one who has submitted.” A Muslim then, is someone who adheres to Islam by accepting and committing to the teachings of the Qu’ran and the Prophet Muhammad. In time, the term Islam came to signify more than just a tradition of faith; it is also used to refer to entire peoples, cultures, and nation-states.

Submission involves the five pillars of the faith:

1. Confession of faith: “There is no God but God, and Muhammad is his Prophet.” Muhammad is regarded as the last and greatest in a line of prophets, including Abraham, Moses, and Jesus.

2. Prayers. Muslims offer prayers five times daily, preceded by ritual purification.

3. Almsgiving. One must give a minimum of one-fortieth of one’s income for the benefit of the poor and the underprivileged in the community; the righteous give more. The Qu’ran repeatedly urges fairness and generosity.

4. Fasting. In the month of Ramadan, nothing may be eaten or drunk between sunrise and sunset (allowances are made for the sick, pregnant women, and travelers). Ramadan marks the month that the Qu’ran was revealed to Muhammad.

5. Pilgrimage to Mecca. The pilgrimage to Mecca involves visiting the site at which Abraham is supposed to have placed a sacred rock. The pilgrimage connects Islam not only with the source of Judaism and Christianity, but also with Arab traditions that precede Islam.

All of the pillars, with the exception of almsgiving (zakat), are matters of ritual. Zakat concerns everyday behavior. The Qu’ran is much concerned with directing the actions of the faithful. It insists again and again on honesty and justice in daily life.

There may be a sixth pillar—jihad. According to some interpretations of the Qu’ran, Muslims must spread the word of Allah and contend with unbelievers. This interpretation is controversial, and some have described
**Islam, Shia and Sunni**

_the concept of jihad is as old as Islam but may be manipulated. In the Qu'ran, it is discussed as a personal struggle (in terms of faith, belief, and virtue). This has been interpreted as a larger struggle against non-believers._

_All Muslims have in common a belief in the scripture. This is particularly important in understanding and approaching Islam as a discursive or textual (rather than oral) tradition, as argued by Talal Asad (1986)._  

**SUNNISM**  
The branch of Islam known as Sunnism was already defined as distinct from Shiism in the eighth century. Sunnis represent nine-tenths of the total world Muslim population. Taking a cue from Marshall Hodgson (1974), one should not consider Sunnism to be mainstream Islam, nor the normative depiction of what is considered Islamic orthodoxy to be represented by Sunnism, with Shiism standing for heterodoxy, Sunnism, as it has been shaped since shortly after the birth of Islam, should be considered a sect of Islam. The followers of this sect are referred to as the “men of the sunnah” (established practice) and the jama'ah (Muslim community). The term is an acknowledgment of the religious power of Muhammad’s companions, and does not refer to the bloodline of Ali and his family. By this definition, Sunnism encompasses the majority of the Muslim community.

_During the eighth century, Sunnis strove to continue the tradition of the Prophet’s daily practices as expressed in the hadith. By the ninth century, Sunni Islam had become well established through schools of law and seminaries known as madrasahs. Sunnis acknowledged the Qu’ran, the hadith, and the sharia (Islamic law) as the basic principles of Islam. The Umayyad caliphate endeavored to establish a belief system that would not differentiate Muslims based on creed or set a specific standard for what it is to be a Muslim._

_For Sunni Muslims, Islam became institutionalized in four schools of law: (1) the Maliki school in North Africa; (2) the Hanafi school, dominant in South Asia, Central Asia, Turkey, Egypt, Syria, Jordan, and Iraq; (3) the Shafi school, established in Egypt and Southeast Asia; and (4) the Hanbali school in Saudi Arabia. Though distinct in approach, all four schools agreed on the basic principles of the faith._

**SUFISM**  
_Literally, the term Sufism refers to the woolen clothing worn by adherents. Sufism dates back to the beginning of Islam when companions of the Prophet sought an ascetic and monastic lifestyle. A strong relationship with God is important to Sufis, who retreat inward while striving to become closer to God and gain a better understanding of Islam. The earliest Sufi master (pir) was Hasan al-Basri (d. 728), a hadith scholar who taught fear of God. Sufism began to take shape among Sunnis in Kufa at the same time that Shiism and Sunnism were developing. In these early years, most Sufis were Sunni. However, Sufis developed strong ties to Shi'ite thought and practice, especially the idea of the imam as infallible and a belief in the imam’s close, esoteric, and mystical relationship with God._

_The concept of a community led by an exalted leader with divine ordinance is central in Sufism, as are spirituality and a personal relationship with God. Sufi forms of worship also differ from those of Sunni and Shi'ite practice. Sufis attend weekly meetings at a place of worship (khanaqah, tekke, or zawiyah) and perform dhikr, which is the union with God through constant repetition of his name. These meetings vary among each Sufi order._

_Sufism grew from a small movement in the eighth and ninth centuries to become an important aspect of Islamic civilization. It was particularly important in spreading Islam to South Asia and Southeast Asia. Most Sufi masters lived by example, but a few actually developed schools of thought. Al-Junayd (d. 910), founder of the school of Baghdad, was the first Sufi Muslim to develop a comprehensive system of Sufi thought. Al-Hallaj (d. 923), founder of the school of Khurasan, became a martyr among Sufis after he was executed by the Abbasid caliph for heresy for proclaiming, “I am haqq” (truth, here meaning God)._  

_By the twelfth century, Sufi orders had begun to develop global followings. Some orders later became politically active (especially in Turkey during the 1920s when they were threatened by Kemal Atatürk [1881–1938]). Others shunned material life and took vows of chastity and purity, all in order to bring them closer to God and truth._

**SHIISM**  
The term Shia refers to followers of Ali. There are several sects within Shiism: the Alids, who believe in Ali as leader of the Muslim community (followers are few and spread throughout the globe but can be found largely in Syria); the Zaydis, followers of Zayd (d. 738), a brother of the fifth imam who established a dynasty in Yemen that lasted until the 1960s; the Isma'ilis or Seveners, considered by many to be militant because of their establishment during the tenth through twelfth centuries of the Fatimid dynasty in Syria and Egypt; and the Twelvers, the largest of the Shi'ite groups, found mostly in Iran, Iraq, and Lebanon.

_The most important event in Shi'ite history is the Battle of Karbala (680). The governor of Syria and Uthman’s cousin, Muawiya urged the Muslim community to accept his son Yazid as the leader of the community. Some of the older families refused to accept Yazid and_
urged Ali’s second son, Husayn, to rebel in the city of Kufah in present-day Iraq. Husayn, the Prophet’s grandson, was belied by the people of Kufah who showed their support for Yazid. Husayn and his small army, which included his family, did not surrender and were pushed out to the desert near the city of Karbala. They were murdered at this famous battle. After this battle, the Shia considered themselves distinct from the Sunnis. The battle also led to the institutionalization of Shiite rituals that commemorate Imam Husayn’s martyrdom, a holiday called Ashura that is held on the tenth of the Islamic month of Muharram. Spectacular passion plays are set each year reenacting Husayn’s martyrdom, leading to what Hodgson called “the piety of protest” and an idealization of martyrdom. Some Shia groups do not participate in such commemorations of the Battle of Karbala.

After the death of Muhammad in 632, Muslims rallied around Ali, who was regarded as the Prophet’s successor. However, the first three caliphs questioned Ali’s succession. The first caliph, Abu Bakr, by establishing the caliphate, stripped the Prophet’s family of its special privileges, an act that challenged the ascendency of blood over community (ummah). Thus, the caliph’s position as head of the community was established shortly after the death of Muhammad.

The second caliphate, headed by Umar, was established in 634 after the death of Abu Bakr. Before his death, Umar urged six men to choose a new caliph. Uthman was chosen and became the third caliph in 644. However, some Muslims considered Uthman to be corrupt and ineffective. According to some sources, Ali began to express disapproval of Uthman’s reign and with his followers formed a party of dissent—the Shia. Thus, the rift between Sunni and Shia developed during the third caliphate. Ali had support in KuFa (in present-day Iraq), and he established his governance there. Muawiyah decided to avenge his cousin Uthman’s death. Muawiya questioned Ali’s role in his cousin’s death because Ali initially refused to avenge his death, preferring to end the bloodshed instead of seeking revenge. What followed were a series of skirmishes and arbitration that led to Muawiya raising a successful army and gaining territory, while Ali lost support, the caliphate, and ultimately his life to kharajites, or seceders. Kharijites are the earliest sect of Islam, who opposed many of the caliphate’s governance.

The Umayyad caliphate, led by Muawiya, sought power after the death of Ali by signing a peace treaty with his son Hasan (625–670). Muawiya, in turn, promised the safety of the followers of Ali. After Muawiya’s death in 680, his son Yazid (c. 645–683) was named his successor, an event that is considered the first dynastic succession in Islamic history. Yazid’s first order of business was to establish unity and allegiance to the Umayyad caliphate. He called on Husayn to give his allegiance to the governor of Medina, but Husayn refused, an act that prompted oppositional movements against Yazid in other cities. Having discovered that his legitimacy as caliph was being questioned by some prominent families in Medina, Yazid decided to crush Husayn and his small army. After Husayn refused to surrender, Yazid’s forces isolated him in the desert near Karbala, where he was killed in battle in 680. That event, along with Ali’s death, confirmed the role of Shites as protesters to tyranny and established power.

For Shia Islam, authority lies in the figure of Ali as imam and caliph, and allegiance and loyalty to Ali and his descendents became a guiding principal. Thus the imamate system is the single most important theological and political aspect of Shiism. Shites developed their own hadith based on Ali’s Nahj al-Balaghah (Path of Eloquence); for Shites, these missives, aphorisms, and sayings of Ali remain words to live by. Shiism also developed its own school of law—the Jafari school, named after the sixth imam, Jafar al-Sadiq (c. 702–765), who established the principle of nas. Nás refers to a special power to gain a deep understanding of the Qu’ran and hadith, as well as the power to pass this knowledge on to the succeeding imam. It is common in Shiism to view the imam as masum, an innocent, flawless leader of knowledge concerning religious truth.

Ali’s line of descendents ended with the twelfth imam, Imam-i Zaman (born in 689, and believe to be still alive in occultation) who was referred to as the nabi, or the messiah, a crucial fact about the imamate system within Shiism. The twelfth imam is believed to have left the earthly world only to return to restore the true faith and to establish justice and a kingdom of God on earth. This view is markedly different from what the majority of Sunni Muslims believe. Sunnis believe strongly in the strength of tradition (hadith) and the agreement of jurists on all matters, as opposed to belief in the piety of Ali and his descendents.

**IS-LM MODEL**

Macroeconomics is a subfield of economic theory that is concerned with the study of economies as a whole. It bears on aggregate variables and is geared toward providing policy advice. The IS-LM model was the prevailing macroeconomic model from the 1950s to the 1970s.

**FROM KEYNES TO HICKS**

The origin of the IS-LM model is to be found in *The General Theory of Employment, Interest, and Money* (1936) by John Maynard Keynes (1883–1946). This book was written in the aftermath of the Great Depression of the 1930s, a time of great disarray, with unemployment reaching peak levels while no remedy seemed to be available to fix the ailing economic system. The general confusion did not spare academic economists, who were torn between their expertise and their gut instincts. According to economic theory, unemployment must have been caused by real wages being too high, so decreasing them should be the remedy. Yet the economists’ instincts told them that this was untrue, and the remedy lay in state-induced demand activation. Keynes’s book aimed at solving this contradiction by providing a theoretical basis for the economists’ gut feelings. The proposed path was to generalize Marshallian theory, which was exclusively concerned with partial equilibrium analysis, so as to enable it to address issues related to interdependency across markets. Keynes’s hunch was that unemployment was due to deficient aggregate demand, the cause of which had its roots in the money market or finance.

Keynes’s book was kaleidoscopic, mingling several threads of reasoning. Its central message was clarified when three young economists—James Meade (1907–1995), Roy Harrod (1900–1978), and John Hicks (1904–1989)—presented their interpretations of Keynes’s book at the European meeting of the Econometric Society in Oxford in September 1936 (see Young [1987] for a vivid account of the event). Of the three papers, Hicks’s (1937) came to prominence. It contained the first version of what was to become the IS-LM model. Hicks succeeded in transforming Keynes’s convoluted reasoning into a simple system of simultaneous equations comprehensible to working economists. Hicks’s paper also included an ingenious graph, allowing the outcome of two distinct markets to be represented in one simple two-dimensional diagram. At the time, Hicks could not have imagined the success his model would later encounter. In effect, it became the organizing theoretical apparatus of the emerging discipline of macroeconomics, in spite of the fact that its ability to capture the central message of the *General Theory* has been questioned by several interpreters of Keynes’s work. Hicks’s original diagram is shown in Figure 1.

This diagram resembles the Marshallian scissorlike representation of the matching of supply and demand in a given market, but its content is totally different. First, it
does not relate to a single market. Second, the two functions it displays are not supply and demand. Instead, it sets the interest rate on the vertical axis, and the aggregate nominal income on the horizontal axis. The downward-sloping IS curve is the combination of income ($Y$ in the subsequent literature) and the interest rate ($r$), for which investment (a function of interest rates) and saving (a function of income) are equal. It is assumed that investment varies inversely with the rate of interest and that saving increases with income. Higher income implies higher saving. As a result, in order for investment to equal saving, the rate of interest must be lower. This explains the inverse relationship between income and the interest rate. The upward-sloping LL curve represents the combination of income and the interest rate that keeps the demand for and the supply of money equal. In the money market, a given supply of money faces a demand for money, which is a function of income and the interest rate. As income increases, the transaction demand for money increases. The other component of the demand for money is liquidity preference. Holding money entails the opportunity cost of foregoing interest on bonds. Hence, the higher the interest rate, the lower this second component of the demand for money. Assuming a fixed supply of money, an increase in income involves a higher transaction demand for money. In order for the total demand for and supply of money to match, the liquidity preference part of the total demand must decrease. This requires a higher interest rate. Hence the upward slope of the LL curve.

Hicks located the essential difference between Keynes and the classical economists in the shape of the LL curve. According to Hicks, Keynes's system becomes “completely out of touch with the classical world” (1937, p. 154) whenever the LL curve exhibits a horizontal section with the IS and the LL curves intersecting on this section. In this situation, which came to be called the liquidity trap, monetary expansion—unlike fiscal policy—is unable to increase employment.

FROM HICKS’S IS-LL MODEL TO THE TEXTBOOK IS-LM MODEL

Hicks's model was not to become the canonical IS-LM model. Franco Modigliani (1918–2003) was the economist responsible for the transition from the Hicks's model to the IS-LM formulation (Modigliani 1944). Another influential economist in this move was Alvin Hansen (1887–1975) (1949, 1953). While dismissing the role of liquidity preference, Modigliani argued that a Keynesian outcome was sure to arise whenever two factors were jointly present: a particular shape of the labor supply curve (supposed to capture the sociological elements that affected the labor supply) and some form of money disturbance, in particular, an insufficient quantity of money. In this recasting, the classical and the Keynesian submodels become more sharply opposed than they had been in Hicks's original paper (see De Vroey 2000). The classical model now featured flexible wages and generalized market clearing, the Keynesian model's downward-rigid wages, and (possibly) involuntary unemployment. According to Modigliani, the Keynesian model is characterized less by a lack of investment than by a maladjustment between the quantity of money and the money wage, the latter being too high relative to the quantity of money. The proper remedy for this situation is an increase in the money supply.

For some twenty-five years after the end of World War II (1939–1945), the IS-LM model dominated macroeconomics. By degrees, standard textbooks adopted the IS-LM model as their framework. It was enriched in various ways by the consideration of open economies, the integration of the Phillips curve, and attempts at giving microfoundations to the consumption function, portfolio decisions, and investment schedules. The success of the IS-LM model can also be explained by its adaptability to econometric modeling.

As the model became more dominant theoretically, it lost its Keynesian character with respect to practical policy issues. That is, non-Keynesians could simply state that only its classical variant was valid, its Keynesian variant being flawed by its ad hoc assumption of rigid wages. Thus, friends and foes of Keynes alike could use the model to promote or refute Keynesian policy prescriptions.

There are several reasons for the success of the IS-LM model. First, it made Keynes's theory tractable. Second, it provided a simplified account of interdependency across markets, allowing the interrelationships between fundamental macroeconomic variables such as income, interest rate, saving, investment, and the supply and demand for money to be studied. Third, the model prompts interesting comparative statics exercises. For example, an increase in the propensity to invest shifts the IS curve to the right, and an increase in the money supply moves the LM curve to the right. Fourth and finally, it has proven to be resilient in the face of criticism.

THE DEMISE OF THE IS-LM MODEL

In the 1970s the dominance of the IS-LM model was strongly challenged as part of a broader offensive against Keynesian theory led by new classical economists, such as Robert E. Lucas and Thomas Sargent. The model's demise accompanied the dethroning of Keynesian macroeconomics, centered on the study of unemployment, and its replacement by dynamic stochastic Walrasian macroeconomics in which the issue of unemployment has only a minor place.

Flaws in the IS-LM model that had until then been overlooked were now fully exposed: the sloppy micro-
-foundations of the model, its lack of consideration for expectations, its lack of connection with long-period analysis, and the inability of macroeconometric models to guide the choice between alternative economic policies.

However, the IS-LM model lives on. While no longer central to the graduate training of most macroeconomists or to cutting-edge macroeconomic research, it continues to be a mainstay of undergraduate textbooks, finds wide application in areas of applied macroeconomics away from the front lines of macroeconomic theory, and lies at the conceptual core of most governmental and commercial macroeconometric models.

ISOLATIONISM
Isolationism can be defined as a state’s deliberate policy of extensive withdrawal and seclusion from some forms of interaction in the international system. Notable examples include the economic isolationism of Japan and China before the nineteenth century and the cultural isolationism of China and the Soviet Union in parts of the twentieth century. In the U.S. context, isolationism has constituted one of the principle foreign policy grand strategies from the founding of the country up to the present day.

EARLY U.S. ISOLATIONISM
From the United States’ inception, isolationists such as George Washington have argued for the benefits of avoiding wars and “entangling alliances” with other great powers at all costs. Military commitments and involvement in the affairs of such states bleed the country of its prosperity. Precious money is wasted on armaments that often antagonize foreign nations. Democratic principles are sometimes suspended and sacrificed in the effort to fight wars. And the United States is unnecessarily distracted from more pressing objectives. “Keep the ships at home,” said Thomas Jefferson (1743–1826), “and we will have fewer reasons to fight.” It was such philosophies that helped keep the United States out of war with European states for most of the eighteenth and nineteenth centuries. Apart from the United States’ relatively minor involvement in the Napoleonic Wars against France from 1798 to 1801, the only war that was fought with a European power was the War of 1812 against the British. Isolationist policies freed America to focus on territorial expansionism in North America, interventionism in Asia and Latin America, and economic activism throughout the globe.

While it is true that U.S. isolationism was assisted by its geographic separation from Europe by the Atlantic Ocean, as Walter Lippman describes in U.S. Foreign Policy: Shield of the Republic (1943), U.S. security during most of the nineteenth century was safeguarded more through a shrewd, unwritten 1823 alliance with Great Britain and the British-led balance of power in Europe than through its geography. Because of Britain’s naval dominance of the approaches from Europe to the Western Hemisphere, Britain was the only force that in theory posed a significant threat to the United States. From the perspective of the British, such an alliance had the advantages of freeing much of its navy to police more critical regions than the Western Hemisphere and to preserve its dominion of Canada from U.S. messianic visions of continental annexation.

When the British-led European balance of power unraveled at the end of the nineteenth century, isolationists nevertheless persisted with the false assumption that the United States was still secure. To avoid a creeping U.S. allegiance to any side in Europe, Congress enacted the Neutrality Acts of 1934 and 1936, which forbade the sale of war matériel to belligerent states. German efforts to dominate Europe during World Wars I and II and Soviet expansionism after World War II nevertheless shattered the illusion of geographic invulnerability. U.S. leaders realized that a single power, such as Germany or the Soviet Union, or a hostile alliance of powers, in control of most of Eurasian military and industrial power, could pose a potentially superior threat. Therefore, the possibility of an unfriendly balance of power against the United States just-
identified a policy of military “preponderance” rather than isolationism (Layne 1997, pp. 88–97).

COLD WAR
When the cold war became the dominant focus of U.S. policymakers, isolationism returned as one among a number of realist strategies, including containment and rollback, which were designed to secure U.S. interests when faced with a menacing Soviet Union. Proponents of cold war isolationism, such as Robert A. Tucker (1972), departed from some of the traditional isolationist arguments. Tucker conceded that isolationism had previously failed to take into account the necessity of having allies. Allies tipped the world balance of power in the United States’ favor by helping to preclude the emergence of a threatening Eurasian hegemon.

Tucker (1972), however, argued that with nuclear weapons powerful allies in Western Europe or elsewhere were no longer necessary. The threat of mutually assured nuclear destruction made concerns about a balance of power irrelevant. Even if the Soviet Union were to somehow conquer Western Europe, Soviet control of the European military-industrial complexes would do little to add to the existing threat posed by a Soviet nuclear first-strike from submarine-based nuclear missiles. In the new nuclear-armed world, the United States was safe from direct Soviet threat because of the deterrent effect of an assured U.S. nuclear counterstrike, not by whether U.S. allies were safe.

Furthermore, it was argued that an isolationist foreign policy is completely compatible with fulfilling an activist U.S. economic agenda abroad since market forces provide the incentives for trade rather than alliances or physical control. For example, even hostile states will be eager over the long run to sell their oil and other goods to the United States—let alone friendly and developed states—whose economies frequently have more to lose through a loss of U.S. trade than the U.S. economic colossus has with respect to them. And with the complete withdrawal of U.S. military commitments from Asia and Europe, those regions will be physically secure from an economically devastating attack, because states such as Germany and Japan would acquire their own nuclear capabilities.

POST–COLD WAR
While the term isolationism may not be so popular today, the assumptions, goals, and remedies that the isolationist concept provides continue to be attractive to many. Modern-day versions of isolationist foreign policy are variously referred to as “disengagement,” “benign detachment,” “policy of restraint,” “offshore balancing,” and “Jeffersonian policy.” Post–cold war isolationists build on the aforementioned cold war arguments. They continue to stress the great costs and dangers of a forwardly engaged military with bases and troops across the globe. Such militarism, they argue, incites terrorism, creates incentives for nuclear proliferation, needlessly wastes money when the United States would be secure anyway, and tends to “turn allies into neutrals and neutrals into enemies” (Gholz, Press, and Sapolsky 1997, p. 37). Like their predecessors, modern isolationists nevertheless agree with limited military engagement. They are in favor of a strong (although significantly reduced) military to fight piracy, defend the homeland, and to ensure the safety of commerce. They believe in maintaining a considerable nuclear deterrent. And they support firm U.S. retaliation in the event of attack. Isolationists, however, continue to be criticized. Critics are uncomfortable with trusting other states to a multipolar balance of power based on nuclear weapons. As the Cuban missile crisis showed, brinkmanship and near misses are still possible even with nuclear weapons. Still, others criticize the isolationists for being immoral and irresponsible in their strong reluctance to forcefully prevent wars, humanitarian emergencies, and genocide. They are also criticized for being careless in protecting U.S. economic interests abroad in the event of future regional conflicts.

The Jacobian matrix was developed by Carl Gustav Jacob Jacobi (1804–1851), a German Jewish mathematician. The Jacobian is a matrix whose entries are first-order partial derivatives defined as

\[
\frac{\partial y_1}{\partial x_1} \quad \frac{\partial y_1}{\partial x_n} \\
\vdots \\
\frac{\partial y_m}{\partial x_1} \quad \frac{\partial y_m}{\partial x_n},
\]

where the function is given by \( m \) real-valued component functions, \( y_1(x_1, \ldots, x_n), \ldots, y_m(x_1, \ldots, x_n) \), continuous (smooth with no breaks or gaps) and differentiable (the derivative must exist at the point being evaluated). If \( m = n \), then the Jacobian matrix is a square matrix. This matrix is denoted by \( J_F(x_1, \ldots, x_n) \).

The interesting concept about the Jacobian is its determinant: Jacobian determinant, \( |J| \). The analysis of the \( |J| \) permits one to characterize the behavior of the function around a given point, which has uses in the social sciences.

First, \( |J| \) is used to test functional dependence, linear and nonlinear, of a set of equations. If \( |J| = 0 \), the equations are functionally dependent. If \( |J| > 0 \), the equations are functionally independent. Note \( J \) does not determine the functional relationship, linear or nonlinear. Second, if \( |J| \) at a given point is different from zero, the function is invertible near that point, that is, an inverse function exists. Then the Jacobian determinant in conjunction with the implicit function theorem can be used to identify changes in an endogenous variable, which may be a choice or optimization variable, as an exogenous variable changes.

Unlike the Hessian, calculating the \( |J| \) becomes laborious as the dimensions of the matrix increase. In addition, the Jacobian is difficult to use with a nonlinear optimization problem, which produces a Jacobian matrix with elements that may not be constant.

JACOBINISM

The Jacobins, founded in 1789 by the Breton deputies to the National Assembly, were the most famous and powerful of the political clubs or societies of the French Revolution. Their official name was the Society of the Friends of the Constitution. They derived their popular name from the house on the Rue St. Jacques where they met in Paris. The bloodiest excesses of the Reign of Terror (1793–1794) can be attributed to their influence and activities. Jacobinism came to denote rabble-rousing radicalism.

Some of the most famous figures of the revolution, most notably Maximilien Robespierre (1758–1794), were members of this society. Many of its leaders served in prominent posts in the Directory of Public Safety that, following the overthrow of the monarchy, ruled France from 1793 to 1794. At first, only deputies, liberal aristocrats, and well-off bourgeois could afford to belong. However, after the reduction of its subscription rates, its ranks were open to the less well off: writers, small shopkeepers, and artisans. The expansion of its membership brought in members with more radical antimonarchical and anticlerical views.

Political clubs grew in popularity as the church and guilds declined. Hundreds of organizations similar to the Jacobin clubs were established from the 1780s to the reign of Napoleon Bonaparte (r. 1804–1815) when they were abolished. They performed many of the functions of a modern political party or party caucus where citizens could meet to discuss public issues, devise strategies, hear speakers, and send delegations to the National Assembly to lobby or threaten.

The mother club in Paris spawned a network of approximately 5,500 Jacobin “cells” in the provinces. These clubs served a variety of roles and functions. They were foremost agents for propaganda-disseminating newspapers, pamphlets, and circulars. As quasi-official units of government, the clubs promoted civic improvement. They held rallies and revolutionary festivals to arouse revolutionary passion and honor the heroes of the revolution. They also raised funds to assist the widows and orphans of revolutionary wars and helped members find jobs. In addition, the clubs operated a spy network to keep an eye on local authorities and émigrés, refractory priests, and other suspected persons. During the Reign of Terror the Jacobins were especially vigilant denouncing persons and purging administrators suspected of antirevolutionary sympathies. Similar to the Communist Party under Vladimir Ilyich Lenin, they were the ideological and organizational heart of the revolution. Their highly centralized organization was held together by their implacable faith in equality and the revolution.

The Jacobins championed republican government, the rule of the people, the abolition of the hereditary aristocracy, popular education, separation of church and state, and universal manhood suffrage. Convinced that the unequal distribution of private goods would lead to political inequality, Robespierre favored fixed limits on the accumulation of wealth. Envisioning a nation of small property owners, however, he opposed the demand of the more radical Enragés for the nationalization of all property. The Jacobins, in their bourgeois phase, believed in laissez-faire economic policies and a qualified right to private property that would exclude émigrés and priests.

All people were created equal, they believed, because they are naturally good and virtuous. Tradition, custom, and religion were condemned as impediments to the attainment of universal equality. Social inequality would be eliminated by the spread of education and enlightened reason. Confident of their personal virtue, the Jacobins condemned their opponents as not only wrong but also evil. Moreover, this “band of the elect” felt obligated to root out political heresies and blasphemies.

As historian Crane Brinton (1961) points out, the Jacobins were mostly prosperous middle-class people who became religious fanatics. After the ascendancy of Robespierre, Jacobinism was transformed into a kind of quasi-religious cult. Robespierre saw himself as the prophet of a new civic religion. He envisioned a spiritual republic, a Republic of Virtue, rooted in “holy Equality and the sacred Rights of Man.” Under his leadership a totalitarian dictatorship was created through the Committee of Public Safety. His religion of virtue would bring a new moral world and the regeneration of humanity. This creed also provided a moral justification for the Terror. Purity became a political fetish. Anyone who did not enthusiastically embrace the new faith was suspected of harboring antirevolutionary opinions and summarily condemned to the guillotine.

The end for the Jacobins came swiftly. As Robespierre’s power grew, his popularity waned. The members of the National Convention, fearing that a new purge would be directed at them, declared him and his associates to be outlaws on July 27, 1794, and had them guillotined the following day. With the fall of Robespierre came the fall of the Jacobins.

The spirit of Jacobin ideas continued in a somewhat altered form in the Directory and later in the Revolution of 1848 and the Paris Commune of 1871. Some of the ideas of the Jacobins persist as a radical opposition to European and North American civilization. They gained a small victory in the Americas when their slogans of “liberty and equality” inspired the 1791 slave revolt in the French West India colony of San Domingo. Called “black Jacobins” by the black Marxist historian, C. L. R. James.
Jacques, Jane

1916–2006

Jane Jacobs was an original American social thinker whose books challenged mainstream views on urban planning and socioeconomic development. Devoid of any professional training, she used her own observations to develop an evolutionary perspective on cities, economy, and society. Jacobs was against social engineering, one-size-fits-all strategies, and big plans; instead, she stressed the importance of the human measure, diversity, and small-scale initiatives for development.

On May 4, 1916, Jacobs was born as Jane Butzner in Scranton, Pennsylvania, where her father was a family doctor. Shortly after graduating from high school she went to New York City and accepted all kinds of writing jobs. In the periods when she was unemployed, Jacobs took long city walks that gave her a notion of what was going on in urban and business life. In 1944 she married the architect Robert Jacobs, with whom she had three children. From 1952 to 1962 Jacobs worked as an associate editor of Architectural Forum; thereafter she was regularly involved in neighborhood activism to oppose urban renewal in New York. In 1969 Jacobs moved with her family to Toronto, where she lived and wrote until her death on April 25, 2006.

Jacobs's most significant works can be divided in two periods. In the first phase (Jacobs Mark I) she published three books on cities. In The Death and Life of Great American Cities (1961) Jacobs portrayed urban life as a “sidewalk ballet” that is served best by diverse, mixed, and densely populated neighborhoods with short building blocks. In The Economy of Cities (1969) and Cities and the Wealth of Nations (1984) Jacobs used urban history and archaeology to show that cities always have been the driving force behind economic development. In the second phase (Jacobs Mark II) Jacobs shifted her attention to socioeconomic issues. Systems of Survival (1992) focused on the moral differences between people working in commerce (“traders”) and politics (“guardians”), whereas The Nature of Economies (2000) dealt with the similarities between the economy and the ecosystem (“biomimicry”); both books were written in the form of a dialogue between fictional New Yorkers. In her last book, Dark Age Ahead (2004), Jacobs warned that the decay of fundamental societal pillars (e.g., family and education) might lead to the deterioration of western civilization.

Undoubtedly, The Death and Life of Great American Cities was Jacobs's most influential work. Her strong critique that traditional urban renewal policy only destroyed communities shocked planners and established Jacobs's reputation as a radical thinker. Her writing style has been called “urban montage” (like snapshots of real city life) and thus is often dismissed as unscientific. Indeed, her analyses are rather anecdotal, unsystematic, and subjective, but that is exactly where their power lies: Unhindered by mainstream thinking, Jacobs could approach urban and socioeconomic issues in a relatively unbiased manner. Therefore it is not so much for the scientific analysis that Jane Jacobs's books still deserve a wide read, but for the provocative and original insights they provide.

Jainism

Currently numbering only about 4.2 million (according to the 2001 census of India), the Jains are an ancient religious community of India. They are basically an urban community, and their largest numbers are found in the Indian states of Gujarat, Karnataka, Madhya Pradesh, Maharashtra, and Rajasthan. Trade is the traditional occupation of Jains, and they are extremely prominent among India’s merchants, especially in the country’s north and west. Contrary to stereotype, not all Jains are rich traders, but many are, with the result that Jains have achieved a degree of economic and political influence in modern India disproportionate to their relative smallness as a community.

The Jains themselves believe their religion to be eternal and thus uncreated. They maintain that it is merely rediscovered by omniscient teachers known as Tirthankaras (fordmakers) or Jinas (victors), that it is something that has already occurred, and will continue to occur an infinity of times, because time itself is beginningless and endless. Modern scholarship, however, traces the origin of Jainism to Lord Mahavira, a genuine historical figure whom Jains consider to be the most recent of the Tirthankaras to have appeared in our region of the universe. Mahavira’s date and place of birth are not certain, although tradition maintains that he was born in 599 B.C.E. in a city called Kundagrama in the Ganges basin near modern-day Patna. It is possible that Mahavira was influenced by the teachings of an earlier figure named Parshva, the only other Tirthankara considered a historical figure by scholars.

Mahavira lived and taught during a period of rapid social change and urbanization in which the Vedic orthodoxy promoted by the Brahman priesthood of those days faced powerful challenges. Wandering ascetics were preaching new religions that devalued Vedic ritualism and emphasized instead the centrality of the individual salvation seeker who renounces the world. Of the nonorthodox traditions that emerged at that time, only two survive as living religions, Jainism and Buddhism, and of these, only Jainism survived in India. As did the other dissenting traditions, Jainism seems to have found special favor among newly emerging urban classes, especially the urban nobility and the merchant class. Merchants (as well as wandering mendicants) played a key role in the spread of Jainism from the Ganges basin to other regions, and royal patronage was an important factor in establishing Jainism in the south.

A major disagreement emerged early in Jainism’s history over the question of whether Jain monks should wear clothing, and the dispute crystallized into a schism in the fifth century C.E. Monks and nuns belonging to the Shvetambara (“white clad”) sect wear white garments; monks (not nuns) belonging to the sect known as Digambara (“space clad”) are nude. The divide between the Digambaras and Shvetambaras has been deep and lasting, and is the principal sectarian divide in Jainism today, with further subsectarian divisions on either side. The Digambaras are especially prominent in South India, with the Shvetambaras strongest in the northwestern states of Gujarat and Rajasthan.

The Jains maintain that the cosmos contains an infinite number of souls (jīvas) that do not perish when the body dies, but are reborn in other bodies. Each soul recycles unceasingly, finding rebirth—as determined by its behavior in life—as humans, denizens of hell, deities, animals, and plants, and even as primitive life forms inhabiting inanimate objects and substances. The cosmos is a vast structure with multiple heavens above and hells below, separated by a small zone where human life is found. Even the gods in the heavens, however, are caught in the same cycle of death and rebirth as all of the other creatures of the cosmos. Indeed, the Jains maintain that because the cosmos was uncreated and will never cease to be, all souls have already inhabited all possible bodies an infinite number of times, and will do so an infinite number of times to come unless liberated from the cycle, which is the ultimate goal of Jain religious life.

The Jains say that karma is the cause of the soul’s bondage to the cycle of death and rebirth. In contrast to other Indic traditions, the Jains consider karma to be an actual material substance that accumulates as an encrustation on the soul as a result of its actions. To attain liberation, therefore, one must bring the accumulation of additional karmic material to a stop and rid one’s soul of past accumulations. Because violent action is a potent cause of karmic influx, nonviolence (ahimsa) is a key strategy in the pursuit of liberation and is the foundation of Jain ethics. However, the attainment of liberation also requires the eradication of already accreted karmic matter. Ascetic practice, for which the Jains are justly famous, is said to “burn away” karmic accumulations, and is a conspicuous feature of Jain life. Once liberated, the soul rises to the apex of the cosmos, where it remains for all eternity in a state of isolated and omniscient bliss.

Jain tradition divides the Jain social order into four components: laymen and laywomen and monks and

Gert-Jan Hospers
nuns. The monks and nuns constitute a small and peripatetic mendicant elite, and although all Jains are supposed to aspire to liberation, the mendicants are viewed as more directly on liberation’s path than are the laity. The mendicants’ daily conduct is governed by five “great vows” (mahavratas): (1) nonviolence (ahimsa), (2) truthfulness, (3) not stealing, (4) celibacy, and (5) nonpossession. All five vows leave a deep imprint on mendicant life, but especially notable are the first and fifth. The vow of nonviolence is the foundation for much of the distinctive character of Jain mendicants’ day-to-day life, which is organized around the need to avoid violence even to microscopic forms of life. For example, they carry special brooms with which to clear living things from surfaces on which they intend to sit or lie, and in some subsects wear masks over their mouths to prevent their hot breath from harming microscopic life forms in the air. The vow of nonpossession cements the lay and mendicant communities into a single social order by ensuring that the mendicants are totally dependent on the laity for their most basic needs, including nourishment, which must be sought from lay households on a daily basis.

Although Jainism was once a proselytizing religion, recruitment today is by birth, and most Jains belong to merchant castes that are Jain or partly Jain in composition. Lay religious life centers on support of mendicants, ascetic practices (especially fasting), observance of Jain calendrical rites, and—in those subsects that permit it—worship of the Tirthankarās’ images in temples. By comparison with the mendicants, the requirement of nonviolence is relaxed for laity, but there are normative minima applying to all lay Jains, and of these, strict vegetarianism is the most essential. Laity do the work of the world and support the mendicant elite, with the result that the mendicants are insulated from the negative effects of the violence that is an inevitable requirement of making a living, food preparation, and simply living in the workaday world. Laymen and laywomen, in turn, benefit from the mendicants’ teaching and from the worldly and spiritual rewards of the merit generated by supporting them.

JAJMANI MATRIX

In two papers published in 1991 and 2004, James G. Scoville analyzed the traditional Indian caste system using a matrix algebra format. Matrix algebra provides a simple way of expressing and analyzing large sets of equations involving numerous variables.

In these papers, Scoville employed a conceptual device called the Jajmani matrix. This matrix, denoted J, has as its elements the flows of goods or services produced by a household of one caste to households of other castes (as well as to itself). Thus, a farming household provides foodstuffs to the carpenter household based on a reciprocal flow of carpentry services; a barber provides haircuts to the washerman based on a reciprocal flow of laundry services. In practice, these transactions are highly complex, but J abstracts from all that complexity and measures (in theory) flows between typical households.

The system of reciprocal flows described is called the jajman system, from the Hindi word for patron. Hence the descriptive adjective is applied to the matrix: Jajmani.

The conceptual utility of the Jajmani matrix is to serve as a key tool in a social accounting framework for the exchange relations associated with the occupational hierarchy of the Hindu caste system. These output and income flows are built into an essentially classical economic model of the traditional Indian caste system. This accounting framework shows the flow of goods and services to a particular caste; one can then compare these flows with some vector of basic needs to see if those needs are met. If there is a surplus, a classical economist might expect that caste’s population to grow; a shortfall would cause that caste’s population to shrink. The mechanism by which caste populations adjust to surpluses or shortages compared to needs is argued to be through changes of marriage rules (age of marriage, number of children, widow remarriage practices). Scoville found some support for the predicted population effects in Indian Census data, and outlined these findings in his 2004 paper.

James, C. L. R.

1901–1989

Cyril Lionel Robert James was born and raised in Trinidad but spent most of his adult life in Britain and the United States. A gifted essayist and speaker, he wrote with great insight on Shakespeare, Melville, Hegel, Athenian democracy, slavery, the Soviet Union, black nationalism, calypso, and cricket. His novel *Minty Alley* (1936) signaled the emergence of a West Indian literary voice, while *Beyond a Boundary* (1963) fused autobiography, sports history, and area studies. He penned a critical study of Soviet foreign policy, *World Revolution 1917–1936: The Rise and Fall of the Communist International* (1937), followed by *The Black Jacobins: Toussaint L'Ouverture and the San Domingo Revolution* (1938), which brought a comparative perspective to the study of the French and Haitian revolutions. James explored U.S. culture and history in *American Civilization* (1950), and lauded a major novelist in *Mariners, Renegades, and Castaways: Herman Melville and the World We Live In* (1953). In *Modern Politics* (1960), he applied Enlightenment ideals to West Indian conditions, while *Party Politics in the West Indies* (1962) leveled a blistering critique of Trinidad’s independence movement. James wrote on West Africa in *Kwame Nkrumah and the Ghana Revolution* (1977). In his final years, he oversaw the publication of three volumes of selected writings, a single-volume reader, and a collection of essays on cricket. In 1988 he was awarded the Trinity Cross, Trinidad and Tobago’s highest national honor.

C. L. R. James embraced Marxism in the mid-1930s, while living in England. He threw himself into political activity and was widely known on the Left for his simultaneous advocacy of socialism and Pan-Africanism. Prior to leaving for the United States in 1938, James edited a Trotskyist newspaper, *Fight*, and the journal of the International African Service Bureau, *International African Opinion*. In the United States in the 1940s he collaborated with a small circle of co-thinkers, the Johnson-Forest Tendency, which staked out an independent radical praxis that characterized the Soviet Union as “state capitalist” and emphasized the creative role of blacks, women, young people, and workers in the making of a “new society.” ("Johnson" was the “party name” for C. L. R. James, while “Forest” was Raya Dunayevskaya, a Russian-born intellectual.) The group produced boldly argued texts on topics ranging from the 1956 Hungarian uprising to Marx’s early writings. While the tendency never numbered more than one hundred members, its ideas prefigured certain New Left positions of the 1960s and 1970s.

James was apprehended by the U.S. immigration authorities in 1952 and expelled the following year. After that, he mainly resided in Britain, although he traveled widely in continental Europe, Africa, and the Caribbean. In the late 1950s and early 1960s he spent nearly four years in Trinidad, playing a high-profile role in the transition to independence. For eighteen months he edited the newspaper of the People’s National Movement (PNM), at the invitation of his old friend and former pupil, Eric Williams, whose landmark *Capitalism and Slavery* (1944) drew on *The Black Jacobins* and benefited from James’s comments on successive drafts. James’s relationship with Williams and other PNM leaders soured as a result of differences over foreign relations and party-building. James left Trinidad on the eve of formal independence, and when he returned in 1965, Williams placed him under house arrest as a dangerous subversive. After his release, James founded the Workers and Farmers Party (WFP) as an electoral challenge to Williams’s rule. The WFP performed poorly in the 1966 elections, and James flew back to Britain.

Since the mid-1990s, there has been an outpouring of scholarship on James’s life and work. Some scholars have focused on retrieving biographical information, and making available unpublished or neglected writings, while others have explored James’s contributions to literary criticism, scholarship on Hegel, cultural studies, and post-colonial studies. A number of authors have emphasized his role as an observer of cultural and historical change; others have focused on his relationship to left politics and historical materialism. Along with Antonio Gramsci, James offers an example of a twentieth-century Marxist whose reputation has risen after the collapse of Soviet Communism. The fact that his name is embedded in the West Indian cultural firmament speaks to the multifaceted character of his complex legacy. There are few modern writers of note who ranged as widely and creatively as C. L. R. James did across the humanities and social sciences.

JAMES, WILLIAM
1842–1910
William James was born in New York City on January 11, 1842, and died in Chocurua, New Hampshire, on August 26, 1910. He was one of the most important and influential American thinkers of the late nineteenth century and early twentieth century and is particularly known for his contributions to the growth of psychology as a scientific field of study and to the school of philosophy known as pragmatism.

CONTRIBUTIONS TO PSYCHOLOGY
James came from a distinguished family. His father, Henry James Sr. (1811–1882), was a philosopher and author in his own right and a close friend of Ralph Waldo Emerson (1803–1882). His younger brother, Henry James Jr. (1843–1916), became a highly regarded novelist and literary figure. In his early years William James experienced a crisis in deciding on a career. He briefly studied art and painting but was convinced by his father to pursue scientific studies instead. While attending Harvard Medical School in the mid-1860s, James spent a year traveling and studying in Germany, and it was during this time that he was exposed to the research being done in that country on the relationship between physiology and psychology, a direction that would lay the groundwork for the emergence of psychology as a scientific discipline.

After returning to Harvard and completing his medical degree, James joined the Harvard faculty in the early 1870s. He served first as an instructor of anatomy and physiology, and then in 1875 began offering a course in psychology based on the ideas he had encountered in Germany. In the same year he established at Boylston Hall one of the first experimental laboratories for psychological research. Among his important early contributions to the field of psychology was his formulation, simultaneous with that of the Danish psychologist Carl Lange (1834–1900), of the James-Lange theory of emotion, which argues that emotion follows, rather than precedes, physiological stimulus. He continued to focus on the study of psychology throughout the 1880s and in 1890 published his great, two-volume work The Principles of Psychology. The work, which had taken him twelve years to write, gained him an international reputation and stands as a landmark in the development of psychology as a scientific field of study.

JAMES AND PRAGMATISM
James's approach to psychology was based on what he later called (in the preface to The Will to Believe, 1897) “radical empiricism.” In this view, human consciousness resembles a flowing stream of undifferentiated objects or data out of which the mind selects specific items, by virtue of personal interest or need, on which to focus its attention. This theory of the mind, and especially its epistemological implications, led James increasingly to the study of philosophy, in which he first offered courses at Harvard in the 1880s, and in particular to the philosophical ideas of pragmatism.

During his earliest days as a teacher at Harvard, James had been part of a group known as the Metaphysical Club that included among its members Charles Sanders Peirce (1839–1914), considered to be the founder of pragmatic philosophy. After the publication of Principles of Psychology in 1890, as James turned more to the investigation of philosophical and epistemological questions in his work, Peirce's ideas influenced his direction. The root assumption of pragmatic epistemology is that theoretical ideas ought to be judged in terms of their practical consequences—if some real benefit accrues from holding a particular idea, then it is valuable; if there is no discernable benefit, it can be discarded. In this view, truth should never be viewed as wholly complete or absolute, because one must be prepared to adjust it to accommodate new information and new understandings.

Although James's best-known discussion of pragmatism appears in the essay collection Pragmatism: A New Name for Some Old Ways of Thinking (1907), an earlier collection, The Will to Believe, and Other Essays in Popular Philosophy (1897), also offers a good expression of his thought. As these titles suggest, James was by no means strictly an academic philosopher but instead sought to make his ideas accessible to a general audience. To this end his essays, often written originally as public lectures, are both interesting and highly readable, and he demonstrates a particular skill in using examples drawn from everyday life. In one of his best known short essays, “What Pragmatism Means” (in Pragmatism), he begins with a story about a group of individuals on a camping trip arguing over the position of a squirrel on a tree and then uses this incident as a way to discuss the pragmatic approach to truth. James also felt strongly that philosophy ought to address the significant social and moral issues of the times. In his essay “The Moral Equivalent of War,” based on a talk he gave at Stanford University in 1906, James argued for a form of organized national service that anticipated the Civilian Conservation Corps in the 1930s as well as later programs such as VISTA and AmeriCorps.

Pragmatism is sometimes seen as a philosophy that destroys any hope of discovering absolute truth and that
leads, through its emphasis on “usefulness” as a primary criterion for establishing truth, to moral relativism. James to some degree anticipated these concerns in his work. Pragmatic epistemology, in his view, remains open to the introduction of new information, especially information resulting from new scientific discoveries, and his application of pragmatic principles to the questions of ethics and even to religion led him to hold highly traditional views on both. In essays such as “The Will to Believe” and “Reflex Action and Theism” (in The Will to Believe) and “Pragmatism and Religion” (in Pragmatism) he set forth the reasons for believing in a theistic God. In fact the study of religion was a matter of considerable importance to James, and his wide-ranging study of religious experience, The Varieties of Religious Experience (1902), made a significant contribution to the study of comparative religion.

JAMES'S LONG-TERM SIGNIFICANCE

James's ideas were extremely significant. They influenced a generation of thinkers who followed him, most notably the great philosopher-educator John Dewey (1859–1952), and they played a role in forming the underlying mind-set—of social experimentation and reform—that characterized the Progressive (1900–1917) and New Deal (1933–1939) periods in U.S. history.

JANATA PARTY

India's Janata Party grew out of the tumultuous political conditions of the 1970s. Following India's military success in East Pakistan in 1971, leading to the independence of Bangladesh, the architect of this victory, Prime Minister Indira Gandhi (1917–1984), led the Congress Party to an overwhelming political victory in the March 1971 national elections. The Congress Party gained two-thirds of the seats in the lower house of parliament, the Lok Sabha. Thereafter, there were accusations of political corruption against Gandhi, arising initially from the charge that she had illegally used the state's political machinery and funds to conduct her election campaign in Allahabad, Uttar Pradesh. When, in 1974, the Allahabad supreme court ruled that she had violated the law, several opposition groups led by Jaya Prakash Narayan (1902–1979) demanded her resignation as prime minister. Widespread demonstrations against Gandhi occurred amidst labor strikes, a slow economy, and public discontent.

Led by Narayan, the head of an opposition socialist party, a group of parties that included the Bharatiya Jan Sangh (BJS), the Bharatiya Lok Dal (BLD), the Rashtriya Swayamsevak Sangh (RSS), and the breakaway Congress Party of Morarji Desai (1896–1995) joined together to form a new party called the Janata Party (the “Peoples Party”). Gandhi's Congress Party was defeated in 1977 by the newly formed Janata Party, ushering in the first non-Congress government of India. Morarji Desai, a former Congress Party finance minister, became the first Janata prime minister. The Janata Party held 270 out of 539 electoral seats in the Lok Sabha. (The total number of seats in the Lok Sabha is 542, including reserved nonelected seats for minorities and backward castes.) Desai's two rivals for leadership, Charan Singh (1902–1987) and Jagjivan Ram (1908–1986), became his deputy prime ministers. The leader of the BJS, Atal Bihari Vajpayee, became the finance minister, and Lal Krishna Advani became the minister for information and broadcasting. Neelam Sanjiva Reddy (1913–1996), a Janata leader, was elected president of India in 1977 upon the death of the incumbent, Fakhruddin Ahmed (1905–1977), thus completing the Janata hold over India's political cabinet and presidency.
The Desai administration lasted from 1977 to 1979, when various splits emerged in the Janata government. The BJS and the RSS wings broke away from the Janata coalition, and the BLD also threatened to leave.

With sufficient coalition partners under the Janata political banner, Charan Singh was sworn in as the new prime minister in June 1979 as leader of the BLD and the new Janata (socialist). But his government did not have a majority in the Lok Sabha, and needed the support of the Congress Party to maintain a majority vote in parliament. Indira Gandhi initially promised to support Singh, but later withdrew the offer, leaving Singh unable to form a government. The Lok Sabha was dissolved and President Reddy called for new elections in January 1980.

Indira Gandhi's Congress Party was swept back into power by an overwhelming majority in 1980. After her assassination in 1984, her son Rajiv Gandhi (1944–1991) became prime minister and achieved a commanding victory in the elections of 1985. However, in the 1989 elections, Rajiv Gandhi's Congress Party was defeated under circumstances similar to those Indira Gandhi had faced. Once again, the Janata-BLD coalition, led this time by V. P. Singh, took power with a narrow majority. The Singh Janata government fell in 1991. Since then, several groups have called themselves the Janata Party or variations of that name. By 2007 the party was most closely identified with the group led by Subramaniam Swamy.

JANOWITZ, MORRIS

1919–1988

The sociologist and political scientist Morris Janowitz was born on October 22, 1919, in Paterson, New Jersey, the son of an immigrant family from eastern Europe. He attended Paterson East Side High School, and in 1937 he enrolled at Washington Square College of New York University, where he came under the influence of the political scientist Bruce Lannes Smith and the philosopher Sydney Hook. He graduated with a degree in economics four years later.

After college, Janowitz worked briefly for Harold Lasswell, who was heading the Experimental Division for the Study of War Time Communications at the Library of Congress. He then went to work for Attorney General Francis Biddle at the Department of Justice Special War Policies Unit. In 1943 he was drafted to serve in the armed forces. He was assigned to the Office of Strategic Services (OSS) in London, and then moved to the General Headquarters (GHQ) of the Allied Expeditionary Forces. He worked on mass communication, morale, and propaganda before being sent to Compiègne, France, where he directed interviews of German POWs. This experience fed his calling as a social scientist, as well as his awareness about issues he would always consider important, such as the inescapability of collective violence and the fabric of social control. The experience also provided data for seminal coauthored papers, including the classic 1948 article, written with Edward Shils, about the effects of primary groups on cohesion and fighting capabilities in the Wehrmacht.

After being discharged, Janowitz was employed briefly as an intelligence analyst for the U.S. State Department. But the advice of friends such as Edward Shils and his own attraction to a stimulating and distinguished academic environment led Janowitz to enroll at the University of Chicago in 1946. He became a lecturer in sociology the following year, and in 1948 he obtained a doctoral degree with his thesis Mobility, Subjective Deprivation, and Ethnic Hostility. It was also at Chicago that he formed close associations with Bruno Bettelheim, William Ogburn, Quincy Wright, Lloyd Fallers, and Edward Shils.

Early in 1951, the same year he married Gayle Shulenberger, Janowitz went to the University of Michigan, where he became full professor in 1957. He returned to the University of Chicago in 1961, where he stayed till his premature death on November 7, 1988. Between 1967 and 1972 he chaired the Sociology Department, helping to restore the prestige it had enjoyed in the past.

JANE CROW

See Jim Crow.
The centrality of the themes Janowitz dealt with and the depth and originality of his thinking gave his scholarship an exceptional quality and made him a major figure in American social sciences. In addition, the variety of his interests is astonishing. He explored issues such as social stratifications, mass communication, propaganda, race and ethnic prejudice, collective action, voting behavior, and the institutional use of armed force (an issue to which he drew other social scientists). His work cut across numerous fields of the social sciences, from psycho-sociology to international relations, and from urban studies to comparative politics. The list of his publications is indeed impressive. Many of his books are now considered to be classic reference works. Among them are The Dynamics of Prejudice (1950, with Bruno Bettelheim), Community Press in an Urban Setting (1952), The Professional Soldier (1960), Institution Building in Urban Education (1969), The Social Control of the Welfare State (1976), The Last Half-Century (1978), and The Reconstruction of Patriotism (1983). His major edited pieces include The New Military (1964), Reader in Public Opinion and Communication (1966, with Bernard Berelson), and Civil-Military Relations (1981). Some of his leading articles have been republished in collections such as Political Conflict (1970) and Military Conflict (1975). These works offer a system of innovative hypotheses, each having a value of its own, at the same time addressing the larger, all-encompassing issues and problematics in the social sciences, giving coherence and logic to the whole. His hypotheses about the modern military—for example, his developments on the changing format of military institutions, comparative models of civil-military relations, or the “constabulary use” of force in contemporary international relation—are illustrative in this regard, for they served both to define the perimeter of a new field of social science inquiry and to orient research on the subject.

One of these central concerns Janowitz touched upon was how the organization and the regulation of societies—never more than an ensemble of loosely aggregated institutions—operate in an orderly manner, especially in constantly changing environments, and especially when subjected to the disruptive forces of modernization. In other words, how can social control, which helps to mitigate self-interest in favor of common values, be maintained, when coercion and socialization have only a limited effect? To grasp such an all-encompassing issue, Janowitz—who considered grand theories inadequate as they postulate more social coherence than in reality—favored an institutional perspective that underlines interorganizational linkages and reciprocations, which, in some circumstances, can be negative, leading to “fragmentation” or “disarticulation,” as with contemporary extended welfare states, for example, affected by lower social cohesion, weakened citizenship, and fragile political legitimacy. At the same time, his analysis is multileveled and shows a preoccupation with micro-macro interactions, without which the complexity of modern society cannot be understood. These include the links between primary groups and larger structures, as well as the formation of social personality, a concept derived from W. I. Thomas to refer to enduring predispositions externalizing the psychic and “which carry over from one interpersonal and social setting to the next.”

Pragmatism was Janowitz’s intellectual standpoint. He was directed to it by Sydney Hook, as well as by his own reading of John Dewey and his familiarity with the outlooks and methods of the Chicago school of sociology. A pragmatic approach provided him with intellectual direction, informed him with the thematic centrality of his sociological concern, and gave him the theoretical and methodological unity his work demonstrates. It also fashioned his career conceptions and his ideas on the social role of a scholar, rejecting on the one hand the “engineering” posture essentially concerned with applied research, and on the other hand the ivory tower style of pursuit of knowledge. He always argued that the social sciences should contribute to the alleviations of social strains, the maintenance of democracy, and effective citizenship by offering the public as well as decision makers reasoned evaluations of problems and possible solutions and policies. He was thus a fervent advocate of the “Enlightenment model.” In this regard, he considered himself a “citizen sociologist,” and his conception of institution building highlights his belief in the public calling of social scientists. He was concerned with searching for renewed forms of social control to cope with fragmented social systems, such as an enhanced civic consciousness, which could emerge from converging reforms aimed at enlarging the professional outlook of the military, education, and justice.

This high sense of responsibility, together with his conception of the academic profession, led him to devise means, both institutional and material, to support, encourage, and expand research. Thus, in 1960 he founded the Inter-University Seminar on Armed Forces and Society, as well as the organization’s quarterly Armed Forces and Society, a leading interdisciplinary journal that has given a strong impetus to the social science study of the military and armed conflict. Similarly his editing of the Heritage of Sociology series offered the academic community important comments and analyses about classical sociological works, beginning with the Chicago school. His challenging teaching and thesis direction are remembered by many who now occupy a prominent place on the academic scene in America and elsewhere.

Japanese Americans

There may well be no other group that simultaneously represents and challenges the meaning of such terms as American dream, model minority, or reparations. These terms are essential to debates about immigration policies, racial politics, and economic opportunities in the United States. Like other immigrant groups, Japanese Americans (Nikkei) embody the struggles, contradictions, and possibilities that are inherent in the promise of a new life in America. And like other nonwhite groups in the United States, the attempts of Japanese Americans to take advantage of what American life promised were met with racism. And like many other U.S. minority groups, racial or not, Japanese Americans have faced an enormous amount of overt and covert discrimination throughout their history. It is here, at the crossroads of U.S. immigration history, racial politics, civil rights struggles, and ideas about economic success, that Japanese Americans, past and present, stand out most starkly.

A MODEL MINORITY

There is no question that Japanese Americans, who began to come to the United States and Hawaii in the late nineteenth century as laborers in the vegetable and sugarcane fields of the Pacific and Western coastal states, could be collectively called an immigrant success story. As the first waves of men arrived, eventually followed by their wives and children, they immediately began to encounter blatant discrimination and exploitation from employers and neighbors, as well as from local, state, and federal governments. They were not alone. The first Japanese immigrants entered the United States at a time when xenophobia, racist nativism, jingoism, and labor struggles helped to create the realities of hardship and survival that give credibility to every American immigration success story. The first Japanese immigrants faced a configuration of the Asiatic Exclusion League, formed in 1908; the Alien Land Laws, passed in 1913 and 1922; the 1922 U.S. Supreme court ruling declaring Japanese ineligible to become naturalized citizens (Ozawa v. United States); the bloody strikebreaking and lockouts in the Hawaiian cane fields during the 1920s and 1930s; and in 1942 the signing of Executive Order 9066, which began the forced removal and incarceration of Japanese Americans during World War II (1939–1945).

When comparing this first generation (Issei) and their children (Nisei) to today’s fourth (Yonsei) and fifth (Gosei) generations, it is not difficult to see why Japanese Americans are considered to be a model minority. The differences between the first and subsequent generations are obvious. And because of the internment of Japanese Americans during World War II, the comparison of the earliest Japanese immigrants to Japanese Americans living in the early twenty-first century is remarkable, and emotionally charged for many. This increasingly multiracial and multiethnic group of descendants, as well as a large number of people who do not claim Japanese ancestry, looks to the history of Japanese people in the United States as representing the best and the worst of what going to America for a better life has meant.

It is not just that Japanese men and women, through their diligence and hard work, laid the framework, both economically and culturally, for their descendants to achieve increasing success with each new generation. That story is part of the immigrant history for many American ethnic groups. Japanese Americans stand out because their history includes the experience of internment, and not only surviving but thriving after being released. As a group, they not only prospered in the postwar years, with a long list of notable and famous Japanese Americans, but they were able to mobilize and achieve redress and reparations in 1988 against a great deal of opposition from the U.S. government. But, like all immigrant histories, the Japanese American success story demands a closer look in order to understand the realities, as well as the images, that give it power and appeal.

Academic research on Japanese Americans has tended to focus on three subjects—the Issei generation, World War II (including internment and Nisei military service), and the redress movement of the 1980s. There are multiple ways of interpreting these episodes, and many stories that remain untold. As interest in the Japanese success story has increased, an attempt to build upon existing understandings and analyses of the varieties of Japanese American histories has unfolded, and with it a desire to expand the ways that Japanese Americans, as individuals and as a group, are seen as part of U.S. history. This effort has cut across disciplinary boundaries and generated a great deal of exciting and often controversial work.

Some scholars have challenged assumptions about who the men and women were that left Japan and what they brought with them as they faced a system of anti-Japanese laws and sentiment in the United States. The assumption that they came with no skills and little education and were able to achieve middle-class status in one (or less than one) generation encourages a look at culture and not economics for an explanation. This is especially important when Japanese Americans are set in stark contrast to other nonwhite and ostensibly nonachieving groups in the United States. Economist Masao Suzuki (2002) makes it clear that the story of Japanese Americans is much more complex than commonly imagined. Focusing on the large out-migration of Japanese back to Japan during the 1920s (the majority of immigrants left) and the ways that the Gentlemen’s Agreement of 1908 regulated and thus changed the type of Japanese immigrant coming to the United States from Japan (the earliest Issei were unskilled farmers; later Issei came with more education and skills), Suzuki argues that the Japanese American immigration story demands contextualization. He argues that lateral mobility, not upward mobility, and selective immigration must be stressed when considering which Japanese Americans achieved economic success, and how they did so. Arguments like this challenge other widely held interpretations that focus on Japanese cultural values by calling attention to the gendered, classed, generational, and regional realities of Japanese Americans before World War II.

INTERNMENT

When President Franklin D. Roosevelt (1882–1945) signed Executive Order 9066 in February, 1942, he did more than direct the removal of more than 120,000 Japanese Americans to desolate areas in the U.S. mainland interior. He helped to create one of the most symbolic moments in both U.S. and Japanese American history.
The internment of Japanese Americans, like the Holocaust, the Great Migration, and the Trail of Tears, is a deservedly major event in U.S. history. Today, the internment is written about widely. This was not always the case, as the subject was not generally discussed in textbooks or in popular culture until the 1980s. This was due, in part, to the decision by many Japanese Americans, though not all, to downplay this injustice.

The removal and four-year incarceration of Japanese Americans led to more than economic hardship and emotional suffering. As they were rounded up and sent to assembly centers in California, Oregon, and Washington with little more than what they could carry—many Issei men were sent to federal prisons without trials or evidence—the meaning of Japanese American began to change. Most were American citizens and minors who were taken to places where their alleged allegiance to Japan would not be a threat to the U.S. war effort. And although such accounts of injustice factor into the ways that internment is useful in arguing that Japanese Americans were a model minority, the incarceration and eventual relocation of Japanese Americans helped to create a generation of Nisei who would never forget the racial injustice that they and their relatives faced during the war. In places like Tule Lake in California and Rowher, Arkansas, some Japanese Americans looked out from behind barbed wire in armed camps and began to rethink what it would mean to be Japanese in postwar America.

Some young Japanese men joined the U.S. military and won numerous medals during the war in an effort to prove their loyalty and make things easier for their relatives. Others, known as the No-No Boys, refused to pledge allegiance or serve in the U.S. military and thus were sent to jail. After the war, some moved as far away from their old lives and the internment camps as possible, creating large postwar Japanese populations in cities like Chicago, where they and their families became part of a new fabric of race, class, and civil rights struggles. During this period, the model minority and success labels began to be applied to Japanese Americans. Yet Japanese American responses to the incarceration indicate that there is a multiplicity of ways that their history can be conceived, both within and outside of the model minority and Japanese American success story images.

REPARATIONS
Beginning in 1970 and ending with the Civil Liberties Act of 1988, the struggles of Japanese Americans to achieve recognition and a token payment for what happened to them during World War II mark yet another moment where the contradictions of the Japanese American immigrant success story are laid bare. There were differing opinions on how to achieve redress, and, as the only racial or ethnic group to be granted an apology and cash settlement from the federal government, this hard-earned victory also helped cast Japanese Americans as a favored minority. As other minority groups, such as African Americans and Native Americans, continue to work for their own reparations, the Japanese American success is held up by a variety of interests who are either demanding or suppressing calls for further reparations acts. What is perhaps most interesting with regard to future claims by other groups was the way that the Japanese American redress initiative was cast—it was about citizenship, not race. Today, the Japanese American Citizen’s League (JACL) continues to frame itself as an organization committed to preventing a recurrence of the civil rights violations that led to the internment. The JACL has, for example, been a loud voice in post-9/11 debates over national security. The images and realities that Japanese Americans embody continue to be of major importance to how life in the United States is imagined and lived.

JAZZ

Jazz is a uniquely American style of music that developed in the early twentieth century in urban areas of the United States. As it grew in popularity and influence, jazz served as a means of bringing young people together. It has always created and sustained artistic subcultures, which have produced new and increasingly sophisticated artistry. As a pervasive and influential musical style, jazz has at times been a great social leveler and unifier. It has melded black and white citizens in a love of fast, rhythmic music, which was first proliferated through radio and the recording industry. Jazz became the basis for most social dance music and also provided one of the first opportunities for public integration.

Jazz first emerged in the black cultures of New Orleans from the mixed influences of ragtime (songs with a syncopated rhythm), blues, and the band music played at New Orleans funerals. The term *jazz* or *jass* derives from a Creole word that means both African dance and copulation. The term *jazz* referring to peppy dance music first appeared in a March 1913 edition of the *San Francisco Bulletin*, an appearance that indicates jazz's rapid spread as a popular musical genre as well as its connection to dancing and nightlife. Developed by such innovative musicians as Buddy Bolden (1877–1931) in New Orleans in the first decade of the twentieth century, jazz had moved west, east, and north to Chicago by 1919. Spread by such New Orleans jazz groups and performers as King Oliver (1885–1938) and his Creole Jazz Band and Jelly Roll Morton (1890–1941), jazz first became popular in the nightclub cultures of big cities. King Oliver's band in Chicago was soon joined by a young Louis Armstrong (1901–1971), who pioneered the rapid rhythmic jazz style called *hot jazz*. White musicians such as Bix Beiderbecke (1903–1931), Jack Teagarden (1905–1964), and Joe Venuti (1903–1978) began to copy the jazz style of New Orleans bands, and soon jazz was an American national phenomenon, appealing to sophisticates and young audiences around the country.

Jazz evolved simultaneously in the 1920s in New Orleans, Chicago, and Kansas City, performed by both black and white ensembles and orchestras. As it developed from its Dixieland forms, jazz styles ranged from the hot jazz of Louis Armstrong to the “symphonic” jazz of Paul Whiteman's (1890–1967) band. Hot jazz, one of the first influential developments of jazz, featured a strong soloist whose variations on the melody and driving momentum were accompanied by an expert ensemble of five or seven players. The idea of soloists playing in relation to backup ensembles also worked easily with larger bands, which began to form in the 1920s.

Fletcher Henderson (1897–1952) and Duke Ellington (1899–1974) established black jazz orchestras that began performing at prominent nightclubs in Chicago and New York. Henderson employed some of the most accomplished jazz musicians of his time, including Armstrong and saxophonist Coleman Hawkins (1904–1969). Ellington, who began as a piano player, established another orchestra, noted for its sophistication in its long-running appearance at New York's Cotton Club. Paul Whiteman, a successful white California orchestra leader, adapted jazz for his larger dance orchestra, which became the most popular band of the 1920s. Whiteman was interested in distinguishing a high art jazz as represented by George Gershwin's (1898–1937) *Rhapsody in Blue* (1924), which Whiteman had commissioned for his orchestra from what he thought of as the cruder jazz of such white jazz ensembles as the Original Dixieland Jazz Band. The Original Dixieland Jazz Band, booked into New York in 1917, was one of the first successful jazz groups.

Live band appearances and a booming recording industry increased jazz's audience, as did Prohibition, which paradoxically made nightlife even more fashionable. Associated with nightclubs and nightlife, jazz became attractively exotic both in the United States and in Europe. Popular jazz bands traveled widely, playing at all kinds of venues from dancehalls and nightclubs to restaurants. The rapidly growing record industry quickly became interested in jazz performers. Such artists as Louis Armstrong, Jelly Roll Morton, Paul Whiteman, Benny Goodman (1909–1986), Duke Ellington, Fletcher Henderson, and others made records that reached audiences who did not venture into city nightlife.

The Great Depression, however, took its toll on smaller and less successful jazz bands, black bands more than white bands. With the advent of *swing* music, many white bands could continue to prosper, but many black bands had more difficulty finding large audiences. They were less commercially successful in general, since most black orchestras did not have the mainstream connections and recording contracts of white bands. In addition, Jim Crow segregation laws kept black orchestras separate from white orchestras. For these reasons, many black jazz musicians went to Europe in the 1920s and 1930s, where they were welcomed. Coleman Hawkins and clarinetist Sidney Bechet (1897–1959) both played in Europe, where audiences were captivated by the erotic suggestiveness of jazz.

Swing, a jazz-inflected dance music, developed in the 1930s and was hugely popular during World War II (1939–1945). Swing jazz was designed for larger musical groups. It continued hot jazz's back-and-forth between a solo player and the supporting ensemble, but it framed and balanced the solo with a more structured accompaniment, which often involved a musical battle between various sections of the band. Swing developed gradually, but
Benny Goodman’s August 21, 1935, performance at the Palomar Ballroom in Los Angeles is often considered swing’s debut. Its popularity established swing as a dance music and style that cut across classes and races. Swing bands—known as *Big Bands*—also employed band singers, many of whom became hugely popular in their own right. Frank Sinatra (1915–1998), for example, caused riots during his appearances with the Tommy Dorsey Band, while Bing Crosby (1903–1977), Ella Fitzgerald (1917–1996), Billie Holiday (1915–1959), Doris Day, and Rosemary Clooney (1928–2002) all became stars in their own right.

Female singers, especially Fitzgerald and Sarah Vaughan (1924–1990), had a larger part in the evolution of jazz than most women did. Since its inception, innovations in jazz seemed to come mainly from those who played wind instruments—trumpet players Louis Armstrong, Dizzy Gillespie (1917–1993), and Miles Davis (1926–1991); saxophonists Charlie Parker (1920–1955) and John Coltrane (1926–1967); and clarinetist Benny Goodman. Players of other instruments, such as piano, drums, bass, and guitar, though enjoying roles as soloists, were primarily responsible for maintaining the driving rhythm of jazz pieces. Until they became prominent as jazz vocalists, women musicians seemed to have little role as jazz artists or innovators. Although they occasionally played in jazz groups, women musicians were most often pianists, such as Louis Armstrong’s wife, Lillian Hardin (1898–1971). The introduction of female vocalists whose role was increasingly like that of other featured wind instruments broadened the dimensions of jazz. *Scat* singing, or singing nonsense syllables, which had been used earlier by Ethel Waters (1900–1977), Edith Wilson (1896–1981), and Louis Armstrong, made the voice sound more like a jazz instrument. Melodic voice improvisation developed by such women vocalists as Adelaide Hall (1904–1993), Ivie Anderson (1905–1949), and most notably Fitzgerald made the voice an instrument and an important part of the jazz repertoire. Vocalist Billie Holiday added her own brand of blues inflected improvisation, phrasing like a wind player and injecting fun and suggestiveness into the music. In the 1940s two other vocalists, Dinah Washington (1924–1963) and Sarah Vaughan, added their own imprimatur to *jazz*: Washington imported a powerful clarity from gospel music, and Vaughan further developed the voice as an instrument in the context of bebop.

The popularity of swing music beginning in the 1930s also enabled bands to cross color lines. Before swing, bands mostly played to audiences of their own race, but with swing, white audiences began to follow black bands as well. In the mid-1930s, Benny Goodman integrated his jazz ensemble, working with Teddy Wilson (1912–1986), a pianist, and Lionel Hampton (1908–2002), a vibraphonist. Because jazz musicians knew, admired, and even borrowed one another’s work, jazz ensembles were among the first integrated public performance groups.

Swing also helped moor up the national mood both during both the Depression and the Second World War. Armed Services Radio broadcast swing music to soldiers. Although musicians and record companies were at a standoff over musicians’ royalties for airplay in 1942, a special V-Disc program produced records for the use of the military.

After the war, many musicians who had begun their careers in swing bands—including Charlie Parker and Dizzy Gillespie—began exploring a more frenetic smallensemble form of jazz known as *bebop*. With such younger artists as Miles Davis and Art Blakey (1919–1990), bebop developed as a more hard-driving, difficult jazz characterized by the prominence of soloists who played rapid complex improvisations in business suits. Bop was primarily the bailiwick of black musicians, who were rescuing the form from the pleasant popularity of swing and who would, with their development of *hard bop* or *bebop* and *cool jazz*, turn jazz into something more intellectual, difficult, and soulful. These later forms became a connoisseur’s jazz, played again in smaller clubs and establishing jazz artists as the avant-garde of music. Such *beat artists* as Jack Kerouac (1922–1969) extolled bop jazz as representing an expression of soul that beat writers wished to emulate by breaking down traditional forms.

Despite its often improvisational character, jazz benefited from a number of talented composers. Instrumentalists such as Bix Beiderbecke, Louis Armstrong, Dizzy Gillespie, Charles Mingus (1922–1979), Miles Davis, Horace Silver, Thelonious Monk (1917–1982), Sun Ra (1914–1993), Wayne Shorter, and Randy Weston contributed to the growing body of jazz music, as did Duke Ellington and his collaborator Billy Strayhorn (1915–1967). Ellington and Strayhorn, both pianists, forged a productive association, writing Ellington’s theme song, “Take the ‘A’ Train” (1941), as well as other well-known favorites played by the Ellington orchestra. More recently, other composers have continued jazz’s evolution, including Jeff Wain and Wynton Marsalis.

Jazz had also long incorporated a broader base of musical styles and influences, so even as it became cool and increasingly sophisticated, it also dipped again and again into a variety of sources, renewing itself and extending its influence into more popular musical forms. As Dizzy Gillespie developed bop, he also infused his music with Afro-Cuban jazz rhythms and musicians. Chano Pozo (1915–1948), a Cuban percussionist, joined Gillespie’s band in 1947, and the addition of Pozo and a wide array of Latin percussion instruments, such as the...
congas, bongos, timbales, and claves, produced complex and rapidly moving pieces. Latin musicians such as trumpet player Arturo Sandoval also joined Gillespie. In the 1950s Puerto Rican percussionist Tito Puente (1923–2000) and Cuban musicians Chico O’Farrill (1921–2001) and Chucho Valdés played Latin mambo in New York, influencing both big band and jazz ensemble sounds. In the early 1960s Brazilian jazz, called *bossa nova*, emerged in the United States. João Gilberto and Antonio Carlos Jobim (1927–1994) brought the style to the United States, and their work was taken up by saxophonist Stan Getz (1927–1991). Miles Davis worked with Brazilian drummer Airto Moreira, and in the 1990s Roy Hargrove incorporated Afro-Cuban elements in his Crisol project. The influence of Latin rhythms and styles enlarged the appeal of jazz, making it more joyous and rhythmic, and via such forms as *bossa nova*, linking it to more mainstream styles.

As jazz became more esoteric, it became more sophisticated than popular. Although it continued to influence the styles of newer music, such as rock and roll, its audience shrank to those who could appreciate its difficulties, and jazz no longer played as direct a role in the evolution of popular music. It retained its links to nightclubs, but lost its aura of carefree joy. Jazz musicians of the 1950s, 1960s, and 1970s became associated with the innovations and countercultural sentiments of the beats. Some, such as pianist Dave Brubeck and saxophonist Paul Desmond (1924–1977), became campus favorites, touring with their jazz quartet around Midwest college campuses in the 1950s. In its links to countercultural art and lifestyles, as well as to a more intellectual milieu, jazz also became associated with civil rights efforts, Black Nationalism, and other radical movements of the 1960s and 1970s. Although jazz musicians (like many performers) had long been linked to drugs and less-than-suburban lifestyles, as drugs became an openly rebellious facet of the hippie and youth movements of the 1970s, they became a part of the myth of jazz as well.

At the same time, jazz also became more academic and respectable as a high culture phenomenon. Music conservatories and universities began offering courses in jazz history and composition and training jazz musicians. Such renowned institutions as the Berklee College of Music in Boston, the Juilliard School in New York City, and the Eastman School of Music in Rochester, New York, as well as numerous universities in the United States and throughout the world, train jazz musicians.

Jazz of the later twentieth century continued to develop multiple styles—free jazz, soul jazz, jazz-rock fusion—that represented attempts to reclaim jazz as a specifically black musical tradition, even though jazz continued to be an integrated effort. Jazz groups again became smaller ensembles and their work became more experimental and aimed at appreciative listeners rather than at dancing. Jazz clubs developed in larger cities; the clubs attract audiences of jazz lovers but not nearly the kind of widespread adulation given to swing. In the 1990s Wynton Marsalis and his brother Branford Marsalis led a renaissance in the widespread popularity of jazz. Wynton Marsalis, a classically trained trumpet player, won Grammy Awards in both classical and jazz categories. More important perhaps was his energetic advocacy of jazz as a central genre of American music. Collaborating with documentary filmmaker Ken Burns, Wynton Marsalis contributed his own more conservative perspective to Burns’s twenty-hour documentary, *Jazz* (2001). Some musicians, such as Miles Davis, thought that Marsalis’s ideas of a pure jazz were too conservative, but Marsalis has certainly been responsible for the revival of jazz as an important musical form.

As it has throughout its history, jazz continues to find talented and innovative musicians who continue to reinvent and redefine jazz. Becoming increasingly international and opening slightly to greater participation by women musicians, jazz continues to influence developing musical styles, but its mixture of styles, its contributions to racial integration, and its establishment of a uniquely American form as a central influential musical tradition already form its legacy.

J-CURVE

A country’s trade balance is defined as the difference between the amount it exports and the amount it imports. When the value of imports exceeds that of exports, the trade balance is said to be in a deficit position. One policy to improve a deficit situation is devaluation; that is, lowering the value of one currency in terms of another currency. By devaluing its currency, a country makes its exports cheaper in terms of foreign currency and its imports more expensive in terms of domestic currency, leading to an increase in export volume and a decrease in import volume. The expansion in exports and retardation of imports are expected to improve the trade deficit. However, for several reasons, after devaluation the trade balance often worsens before improving. Since this pattern of movement of the trade balance over time subsequent to devaluation resembles the letter J, economists have termed it the J-Curve phenomenon.

Several factors contribute to the J-Curve effect. First, at the time of devaluation, commodities in transit are priced at the old exchange rate. If the trade balance had been deteriorating before devaluation, it will continue to deteriorate after devaluation. Only after the passage of some time when new prices begin to prevail at the new exchange rate will the trade balance improve. Second, at the time of devaluation a country could experience a rapid increase in its economic activity, leading to economic growth. Since a growing economy consumes more of not only domestically produced goods but also of imported goods, its imports could rise substantially. The increase in imports may offset any favorable effects of devaluation, resulting in a short-run deterioration of the trade balance. Finally, devaluation is expected to increase the volume of exports and reduce the volume of imports. However, the adjustment of export and import volumes to a change in the exchange rate may occur with some time delay or adjustment lags. For example, there may be lags in delivery time, lags in replacing inventories, and lags in adjusting the production process.

The J-Curve effect was first observed in 1973 by Stephen Magee when the U.S. trade balance deteriorated in 1972 despite devaluation of the dollar in 1971. One question researchers have raised is how long it takes for the trade balance to experience an improvement after devaluation. In an effort to provide an answer to this question, in 1985 Mohsen Bahmani-Oskooee was the first to introduce a method of testing the J-Curve phenomenon by directly relating the trade balance to the exchange rate in addition to other determinants. Early studies employed aggregate trade data (i.e., export and import data between one country and the rest of the world) to test the phenomenon. Generally, these studies provided mixed results and were criticized as suffering from aggregation bias. To overcome the problem, a second group of studies concentrated on the trade between one country and each of its major trading partners, a disaggregation at the bilateral level. This group was able to discover more evidence in support of the J-Curve. A few studies in the last decade have disaggregated the trade data further by investigating the response of trade flows to exchange rate changes at the commodity level. These studies show that the phenomenon could be commodity specific.

Recent advances in time-series analysis have helped researchers to modify the definition of the J-Curve as a short-run deterioration of the trade balance and a long-run improvement. This definition extends the original definition of the J-Curve and is in line with more recent advances in econometric modeling such as error-correction and cointegration techniques. Generally, the error-correction specification of any model tests the short-run dynamics while cointegration tests the long-run effects. The modified definition and application of modern techniques generally provide strong support for the phenomenon.

JEFFERSON, THOMAS
1743–1826

Thomas Jefferson's interests and pursuits presaged many substantive and methodological concerns of the modern social sciences. Jefferson exemplified the spirit of the Enlightenment—that great, diverse intellectual movement that dominated Atlantic civilization from the late seventeenth century to the dawn of the nineteenth century. The sorting and synthesizing habits characteristic of Enlightenment thought formed the core of his thinking. Not just intellectual curiosity spurred Jefferson, however. The challenges posed by the American Revolution (1775–1783)—creating a new nation, defining its form of
Jefferson, Thomas

government and politics, and shaping the kind of nation that the United States would become and the kind of people it would have—lent practical urgency to Jefferson’s investigations of the natural, social, and political world.

Jefferson was born in Shadwell, Virginia, on April 13, 1743, the son of a gentleman planter determined to secure the best possible education for his son. At the College of William and Mary, Jefferson found his two mentors. Professor William Small (1734–1775) introduced Jefferson to Enlightenment thought and the study of natural philosophy (his era’s term for science), and the attorney George Wythe (1726–1806) inspired Jefferson to join the bar. Wythe supervised Jefferson’s legal training, insisting that he not only master the law but see it as a learned profession. Under Wythe’s tutelage, Jefferson situated his legal knowledge within a wide and deep classical, historical, and philosophical education. Though his legal practice lasted less than a decade, his legal training continued to shape his work as a politician and a scientific and political thinker.

Jefferson’s lifelong commitment to public service began with his election in 1768 to the Virginia legislature. Jefferson watched with anxiety the growing dispute between Great Britain and its North American colonies over the scope of British power to tax the colonists and legislate for them. In 1774 Jefferson drafted a set of instructions for the Virginia delegation to the First Continental Congress. His draft, judged too radical, nonetheless appeared as a pamphlet, A Summary View of the Rights of British America. Jefferson’s eloquence and cogency won him acclaim, but his willingness to lecture King George III (1738–1820) on his duty to his American subjects provoked hostility in London.

In 1775 Jefferson was named a Virginia delegate to the Second Continental Congress. Though he rarely took the floor, he won his colleagues’ respect by his ability as a draftsman to synthesize their clashing views. His ultimate challenge came when, in June 1776, Congress named him to a committee, with John Adams (1735–1826), Benjamin Franklin (1706–1790), Robert R. Livingston (1746–1813), and Roger Sherman (1721–1793), to draft a declaration of independence; the committee assigned the task to Jefferson. Jefferson always preferred his draft to Congress’s version, complaining that Congress had ruined his work by cutting key portions of his argument, including a passage blaming George III for the American institution of chattel slavery; by contrast, most historians maintain that Congress’s edits improved the document’s cogency and force. The Declaration of Independence has three parts: (1) a preamble invoking Lockean social-contract theory to lay the intellectual groundwork for the Americans’ assertion of the right of revolution; (2) an indictment of George III for violating the unwritten English constitution as the Americans understood it, thus dissolving Americans’ obligations to remain loyal to him; and (3) a closing incorporating the congressional resolution declaring independence. The Declaration looks backward, tying off the constitutional argument with Great Britain, and forward, delineating the core principles of an independent America. Further, the eloquent preamble of the Declaration inspired democratic revolutions for generations thereafter.

Recognizing that independence required legitimate government, Congress authorized the thirteen colonies to frame new constitutions. For Jefferson, new-modeling constitutions and laws was integral to creating a good American society. Sweeping away such vestiges of feudalism as primogeniture (a system of inheritance naming the oldest son sole heir) and entail (a system of land ownership allowing the original owner to restrict transfer of his lands to heirs of his family) would, he thought, advance the cause of democracy and republican government. The resulting society would be a true republic committed to the ideals of the Revolution.

For these reasons, when he returned to Virginia, Jefferson focused his energies on legal reform. With his mentor George Wythe and Wythe’s rival Edmund Pendleton (1721–1803), Jefferson launched a project to revise the state’s laws. Their 1779 report included such pathbreaking proposals as Jefferson’s “Bill for Establishing Religious Freedom,” his “Bill for Proportioning Crimes and Punishments,” and his “Bill for Establishment of a System of Public Education.” This compilation crystallized Jefferson’s vision of the good society, forming his political agenda for Virginia for the rest of his life. The legislature, however, tabled the report. In the 1780s, Jefferson’s ally, James Madison (1751–1836), spearheaded efforts to enact some of the report’s bills, including the 1786 Act for Establishing Religious Freedom.

Two of the three key measures of Jefferson’s lawmaking had to do with the life of the mind and individual liberty; all three embodied his devotion to Enlightenment ideals. Arguing that any alliance between church and state was dangerous to individual liberty and the health of the political realm, Jefferson insisted on strict separation of church and state, denying government any power to direct what citizens should believe or do in matters of religious belief and observance. Jefferson’s proposed system of public education embodied his view that an informed citizenry was essential to the success of republican government. Finally, his measure for proportioning crimes and punishments reflected the profound influence of Marquis Cesare di Beccaria’s (1738–1794) Treatise on Crimes and Punishments (1764), in particular Beccaria’s commitment to humanizing law and setting aside old,
barbarous punishments as inconsistent with a modern, just legal system.

In 1779 the legislature elected Jefferson governor of Virginia—a post with many responsibilities but little power. Jefferson served two one-year terms, but in 1781 his governorship’s closing weeks, when he faced a British invasion of Virginia, provoked criticism souring him on public life, and he decided to retire. One incident of his governorship has lasting significance for his role in the social sciences. François de Barbé-Marbois (1745–1837), a French diplomat, sent the governors of all thirteen states a questionnaire about each state’s geography, history, resources, people, and laws. Jefferson restructured this list of queries and made it the skeleton of his only full-length book, Notes on the State of Virginia, which occupied him, on and off, for the next six years. It distracted him from his sorrows after his wife’s sudden death in 1782, and it gave him an intellectual focus while he returned to public life, first as a delegate to the Confederation Congress and then as American minister to France (1784–1789).

Published privately in Paris in 1785 and in a revised form in London in 1787, Notes on the State of Virginia embodied the spirit of the Enlightenment. It gave Jefferson the chance to advocate some of his cherished ideas, such as the need for religious liberty and separation of church and state, the excellence and desirability of republican government, and his love for his native land, which he promoted as a welcoming refuge from the corruptions of the Old World and a model of what a good society could be. Jefferson offered a powerful defense of America against the strictures of such European thinkers as the Comte de Buffon (1707–1788), who argued that nature and humanity degenerated in the New World. In particular, Jefferson defended Native American peoples against charges that they were lesser beings than Europeans, foreshadowing his lifelong interest in ethnography. At the same time, Notes presents Jefferson’s agonized struggles with the issue of slavery. Jefferson, himself a slaveowner, wrote eloquently about slavery’s injustice but offered a tortured case for slavery based on his claim that people of African descent were inferior to Europeans in intellect, morals, and physical beauty, and thus could not be trusted with liberty. Though such thinkers as Immanuel Kant (1724–1804) and David Hume (1711–1776) had voiced racist views of Africans, these were casual asides. By contrast, Jefferson expounded a defense of slavery based on what later generations would call “racial science.”

While Jefferson was in France, he began a sexual relationship with his slave Sally Hemings (1773–1835), a daughter of Betty Hemings (1735–1807), who had been both the slave and the mistress of Jefferson’s father-in-law. (Thus, Sally was half-sister to Jefferson’s wife, Martha Wayles Skelton Jefferson [1748–1782].) The teenaged Sally Hemings came to France with Jefferson’s younger daughter, Maria Jefferson (1778–1804), whom he had summoned to live with him and his older daughter, Martha (1772–1836). According to Sally Hemings’s son Madison Hemings (1805–1877), the two became lovers in France, and Sally extracted from Jefferson a promise that if she returned with him to Monticello, he would free all her children. The liaison continued for more than two decades. When Jefferson died, the only slaves that he freed were children of Sally Hemings and others connected with the Hemings family.

During Jefferson’s presidency, James Thomson Callender (1758–1803), a muckraking journalist furious that Jefferson had not rewarded his support with a government job, revealed the Jefferson-Hemings liaison in the Richmond Enquirer. Jefferson’s allies, family, and most biographers rejected the accusation as a political smear. In 1997, however, Professor Annette Gordon-Reed of New York Law School reexamined the evidence and the controversy’s history, challenging assumptions that influenced previous scholars (such as “black people lie, white people tell the truth” and “slaves lie, slaveowners tell the truth”). Her rigorous assessment convincingly showed that the Jefferson-Hemings liaison was more probable than not. In 1998 a DNA analysis of evidence from descendants of Eston Hemings (1808–c.1853) and descendants of Jefferson’s uncle Field Jefferson (1702–1765) found a match indicating that a male member of Jefferson’s family was the father of Eston Hemings. That finding, combined with Gordon-Reed’s analysis of the historical evidence and the discovery that every time Sally Hemings gave birth Jefferson was in the vicinity nine months before the delivery, reversed the scholarly consensus from rejection to acceptance of the liaison between Jefferson and Hemings.

While he served as American minister to France, Jefferson became a mentor to such French politicians as Lafayette (1757–1834) and Mirabeau (1715–1789). Indeed, in 1789 Jefferson was an informal adviser to the drafting of the French Declaration of the Rights of Man. He also traveled widely in Europe; his travel diaries and letters reveal him to be an astute observer of society and politics. His letters’ recurring themes include his contrast of European corruption with American innocence. His approval of the French Revolution (1789–1799)—though its excesses horrified many of his friends, such as John and Abigail Adams (1744–1818) and William Short (1759–1849)—was rooted in his conviction of the horrifying injustices perpetuated by the ancien régime and his belief that revolutionary violence was not too high a price to pay to end those abuses.

In late 1789 Jefferson returned to America for a leave of absence. Instead, he accepted President George
Washington's (1732–1799) offer of the post of secretary of state in the new government under the Constitution. When Jefferson took office in May 1799, still in the grip of his impressions of Europe, he was horrified by what he found. In his eyes, Americans were falling under the spell of corrupting doctrines from Great Britain privileging commerce and speculation, undermining his vision of an honest agrarian republic of yeoman farmers. These realizations caused Jefferson to become increasingly doctrinaire and rigid.

The fiscal policies of Treasury Secretary Alexander Hamilton (1755–1804) formed the first flashpoint of contention, followed by clashing views about America's relations with the revolutionary French Republic. Unlike Jefferson, the prophet of agrarian democracy, Hamilton argued for a national economic system in which agriculture, trade and commerce, and manufacturing would form the three pillars of a healthy and prosperous nation. Hamilton also favored a vigorous national government— which Jefferson saw as a threat to American liberty. Finally, Jefferson hailed the French Revolution as the first salvo of a worldwide democratic revolution that he hoped would reshape the world, whereas Hamilton saw it as a threat to stability, religion, property, and good order—the props of a stable republic.

Until Jefferson stepped down from Washington's cabinet at the end of 1793, and for a decade thereafter, his epic political and constitutional battles with Hamilton helped to define key polarities of American politics—strict versus broad interpretation of the Constitution, agrarianism versus commerce and trade and industry, and decentralized versus centralized government. In response to what he saw as Hamilton's threat to liberty, republican government, and the success of the American Revolution, Jefferson and Madison helped lay the groundwork for partisan politics under the Constitution. Frustrated and exhausted by partisan battles, Jefferson retired in 1793, not returning to politics until his election as vice president in 1796, under his old friend and political adversary, President John Adams.

The Adams presidency was plagued by strife over the French Revolution and the wars convulsing Europe. Facing the quasi-war with France (1798–1800), the Adams administration rammed through Congress laws restricting rights of aliens and defining federal power to punish criticism of the government. Jefferson and Madison covertly penned two sets of resolutions against these measures that the Kentucky (Jefferson) and Virginia (Madison) legislatures adopted. These resolutions argued that the federal laws were unconstitutional and that the states had varying means to resist unconstitutional federal laws, helping to fuel generations of controversy over the nature of the American union and the powers of the federal government over the states.

In 1801, after an electoral deadlock that threatened to shake the government to its foundations, Thomas Jefferson was sworn in as the nation's third president. With the support of solid Republican majorities in Congress, Jefferson set out to undo what he viewed as Federalist corruption of American principles, outlining in his inaugural address his approach to American government: “a wise and frugal government” overseeing a union of states that would keep its distance from the wars convulsing Europe.

When Jefferson took office, access to the Mississippi River was a key political and diplomatic issue. Determined to secure that access and American claims to the trans-Mississippi West, Jefferson devised a combined scientific and military expedition, blending the goal of scientific research into the geography, flora, fauna, and native peoples of the region with the equally important goal of assertion of American power. At the same time, he sent American diplomats to Paris to find a means to acquire the vital port of New Orleans. By good fortune and deft diplomacy, these diplomats secured from France the entire Louisiana Territory, including New Orleans. Jefferson then set in motion his plans for the expedition, to be commanded by captains Meriwether Lewis (1774–1809) and William Clark (1770–1838). Jefferson's confidential instructions to Lewis set an ambitious research agenda and became a model for all later American expeditions of science and discovery. The Lewis and Clark expedition ranks with the Louisiana Purchase among the greatest achievements of Jefferson's presidency.

Jefferson's first term was notably successful, in great measure because he could control the development of events; his second was less so, as increasingly he had to react to events beyond his control in the international realm. Seeking to end European hostilities threatening American shipping, Jefferson imposed an embargo on the warring nations, hoping to use American economic power to coerce Britain and France to make peace. The policy backfired, forcing Jefferson to adopt ever-more draconian enforcement measures, creating the very model of a strong central government that he had so long opposed. It was with relief that he retired from the presidency in 1809.

Jefferson's life followed a pattern of ventures into public life followed by retreats into retirement at his home, Monticello. In the early 1770s, Jefferson leveled a hilltop inherited from his father and began to build a house, deriving its design from the works of the Italian architect Andrea Palladio (1508–1580), himself strongly influenced by classical models. Not only did Palladio please Jefferson's aesthetic sense, his work echoed Jefferson's belief that classical architecture fostered values
associated with the Athenian democracy and the Roman Republic. For a decade, Jefferson worked to make Monticello a model of classical refinement. When in 1789 he returned from France, he recast his plans for Monticello; from 1793 to the early 1820s he undertook a massive program of pulling down and building up—a plan interrupted by his service as vice president, continued in fits and starts during his presidency, and resumed after his retirement in 1809. In this period, Monticello acquired its present form—a house designed to appear from outside as a single story, with a low dome and porticos on both fronts. Monticello also was a stage set where Jefferson could welcome visitors as the sage of Monticello.

Monticello is only one of Jefferson's architectural achievements. The second example is the Virginia capitol, which he modeled on the Maison Carrée at Nîmes, France. The third example is Jefferson's country home, the octagonal Poplar Forest, completed in 1809, which was his refuge from the pressure of visitors at Monticello. With the University of Virginia, these projects were pivotal in popularizing classical ideas and ideals of architecture in the United States.

The former president became a figure of interest for the hundreds of travelers and fellow-citizens who hoped to meet him. He also dealt with a massive correspondence, "drudging at the writing-table" (as he told John Adams, with whom he resumed friendship in 1812). Jefferson used his letters to explore issues of democracy and republican government that had preoccupied him since the Revolution. He argued that laws and constitutions must change with changing times and circumstances and that each generation ought to be able to make its own laws and create its own government without being held hostage by the work of previous generations. Dearest to his heart was his idea that society and government should be divided into wards or hundreds, which would form counties, which would form states linked together in a union of shared affection, sentiments, and interests and needing only a weak government to superintend foreign relations. Jefferson was not a rigorous political theorist, however, and never produced a sustained work of political philosophy.

Jefferson devoted his last years to two great endeavors in the social sciences. Building on the work of his friend, the chemist and theologian Reverend Joseph Priestley (1733–1804), he prepared a short book for his own use, The Life and Morals of Jesus of Nazareth, removing from the Gospels what he deemed false and fraudulent material attributable to "priestcraft." Published for the first time in 1804 by Congress, this book, a pioneering example of historical criticism of the Bible, has acquired the (mistaken) title The Jefferson Bible.

Closest to Jefferson's heart, and in many ways his last great struggle, was his campaign to create a new university for Virginia, not allied with any religious sect or denomination. It was the capstone of his plan of a system of public education, but he now realized that the university was all that he would have a chance to create. At Jefferson's urging, the Virginia legislature created a commission that he would chair. He wrote its report, shepherded it through the legislature, and began to design the University of Virginia. He picked the professors, defined the curriculum, laid out the campus, and designed all the buildings. When it opened in 1825, with Jefferson as its first rector, it was the culmination of his life's work.

Jefferson died on July 4, 1826, the fiftieth anniversary of the adoption of the Declaration of Independence, at the age of eighty-three. A few hours after he died, his friend and fellow signer of the Declaration of Independence, John Adams, died at the age of ninety. The coincidence of these deaths seemed to their fellow citizens an event of almost biblical proportions, as if the almighty had called the two patriarchs to heaven to honor their political labors.

In his epitaph, drafted in the last months of his life, Jefferson codified his legacy: "Author of the Declaration of Independence and of the Virginia Statute for Religious Freedom, and Father of the University of Virginia." This summation distilled his commitment to the revolution of ideas that reshaped the world in the late eighteenth century. In addition, these achievements helped to shape a world in which the social sciences could evolve into powerful tools by which human beings could come to understand their world and reshape it for the better. And yet, Jefferson's life and thought also show the dangers as well as the hopes of uncritically relying on the social sciences to make the world anew.

Christopher Jencks is among the most widely respected and influential social scientists in the United States. His career has been driven by an interest in economic opportunity and the welfare of individuals at the bottom of the income distribution. Following a brief tenure as a high school teacher, Jencks entered the social policy world in the early 1960s as a self-described “journalist and political activist,” working at The New Republic and the Institute for Policy Studies, a left-leaning Washington, D.C., think tank. The public impact of the “Coleman Report” (Coleman et al. 1966) impressed Jencks with the power of fact-based social science research to influence public attitudes. He subsequently began a distinguished academic career marked by an adherence to data-driven conclusions that challenge the preconceptions of all ideological perspectives.

He joined the faculty of the Harvard Graduate School of Education’s newly formed Center for Educational Policy Research in the late 1960s, where he and his collaborators produced Inequality: A Reassessment of the Effect of Family and Schooling in America (1972) and Who Gets Ahead? The Determinants of Economic Success in America (1979). Inequality challenged the received wisdom that equalizing educational opportunities would eliminate economic inequality by showing, not uncontroversially, that while both schools and family background have sizable effects on economic success, they still explain only a modest fraction of the total variation in income. Who Gets Ahead? argues for the importance of cognitive skills and personality, though it also highlights the roles of family background and schooling. The findings in these volumes catalyzed much subsequent research on the causes of economic inequality and on policies to reduce inequality.

In his influential 1992 book, Rethinking Social Policy, Jencks focuses on a set of policy issues that had risen to prominence in the preceding decade—including affirmative action, welfare, and the “underclass.” His measured analyses aim to both illuminate and temper debates over those controversial issues by, as he writes, “unbundling the empirical and moral assumptions that traditional ideologies tie together” (Jencks 1992, p. 21). For example, while the nature versus nurture debate polarizes individuals on opposite ends of the political spectrum, Jencks argues that the question is neither completely resolvable—since the two interact—nor necessarily relevant to deciding what policy choices are best for dealing with poverty and inequality. Jencks’s research has also challenged the validity of income-based measures of poverty, instead arguing for increased government efforts to directly track material hardship. His ensuing policy recommendations regarding the safety net emphasize both the importance of the responsibilities of society to its members and those of individuals to the collective.

The Homeless (1994) attributes the rise in the number of homeless people in the United States during the 1980s to the deinstitutionalization of the mentally ill, the crack-cocaine epidemic, the rise in long-term joblessness, the decline in the value of welfare benefits, the decline in marriage among women with children, and the decline in the availability of cheap “skid row” housing. It also proposes a series of policies aimed at different groups within the homeless population.

Jencks returned to the potential of human capital policies to reduce inequality in his edited volume (with Meredith Phillips), The Black-White Test Score Gap (1998). Contrary to his prior assertions that human capital policies would have little effect on reducing inequality, he argues that “reducing the test score gap is probably both necessary and sufficient for substantially reducing racial inequality in educational attainment and earnings” (Jencks and Phillips 1998, p. 4). This new conclusion is warranted because “the world has changed” (p. 4).

In addition to his empirically based analyses, Jencks has contributed to philosophical perspectives on the meaning of equal opportunity. Seemingly all political groups in the United States support the ideal of equal opportunity. In his essay, “Whom Must We Treat Equally for Educational Opportunity to be Equal” (1988), Jencks shows that the apparent consensus is due to the multiple meanings attached to the term. While equal opportunity’s
popularity is largely due to its pliancy, Jencks laments that this impreciseness ultimately renders it of little use as a guide to policy.

After a career focused on the causes of inequality, Jencks turned his attention to its consequences for social outcomes such as family structure, educational attainment, and civic engagement. Jencks is known for his clear, penetrating writing style, and he frequently publishes in nonacademic venues such as The New York Review of Books and The American Prospect, where he serves on the editorial board. His numerous awards and honors include four book awards and memberships in the National Academy of Sciences, the American Philosophical Society, and the American Academy of Political and Social Science. Jencks has been the Malcolm Wiener Professor of Social Policy at Harvard University’s Kennedy School of Government since 1998.

JERVIS, ROBERT

1940–

Robert L. Jervis, the Adlai E. Stevenson Professor of International Politics at Columbia University since 1980 and president of the American Political Science Association (2000–2001), has been a leading ﬁgure in academic research on war, peace, and diplomacy. His theories explain how misperceptions, unintended consequences, and competitive dilemmas often confound the efforts of political leaders and strategists to escape from the insecurities of international competition.

The Logic of Images in International Relations (1970) introduced the distinction between signals and indices in strategic bargaining, later referred to as “cheap talk” and “costly signals.” Perception and Misperception in International Politics (1976) assessed the applicability of a wide range of psychological propositions to the study of deterrence failures, conﬂict spirals, intelligence failures, strategic assessments, and diplomatic judgments and misjudgments. The central message is that perception is theory-driven, that decision makers tend to see what they expect to see, and that these expectations are often driven by stereotyped lessons of history, analogies, or routine scripts that provide short cuts in making assessments under uncertainty. Jervis examines common perceptual biases, such as the cognitive shortcuts that lead actors to overestimate the extent to which their opponents intend the harmful consequences of their actions and underestimate the extent to which those actions are a reaction to the observers’ own initiatives.

Jervis’s most cited article, “Cooperation Under the Security Dilemma” (1978), draws on Jean-Jacques Rousseau’s (1712–1778) parable of the stag hunt and the prisoner’s dilemma game to show how states seeking only to defend the status quo can end up ﬁghting due to the fears engendered by the situation of anarchy. Jervis deﬁnes a security dilemma as a situation in which any state’s efforts to increase its security necessarily decreases the security of others. In this situation, one side’s efforts to escape its insecurity through an arms buildup or through the conquest of strategic territory will inevitably trigger similar
behavior by other security-conscious actors. Both strategic circumstances and the whole array of perceptual biases discussed in Jervis’s earlier work shape behavior under the security dilemma. Offensive military technology and barrier-free geography heighten vulnerability to attack and thus intensify the security dilemma. Strategists and political leaders often misestimate the ease of attacking or defending, misperceive the balance between offensive and defensive incentives, and err in their judgment of the likelihood that the other “stag hunters” will defect from cooperation.

Applying these ideas to the problem of nuclear deterrence, Jervis explained why nuclear war-fighting is a delusion and how a stable balance of terror relaxes the security dilemma. While building on earlier theories of deterrence, Jervis added important new insights by drawing on new ideas from cognitive psychology. For example, psychologists have found that most people are risk-averse when faced with the chance to grab gains, but are more risk-acceptant in forestalling losses. Thus, Jervis reasoned that the side defending the status quo, and in particular the side defending its vital interests, should be more willing to run the shared risk of mutual annihilation. If so, the nuclear stalemate ought to make threats to change the status quo less credible and consequently should ease the security dilemma. In 1990 Jervis’s *The Meaning of the Nuclear Revolution* (1989) won the Grawemeyer Award for the book with the Best Ideas for Improving World Order.

Jervis received his BA from Oberlin College in 1962 and his PhD from the University of California, Berkeley, in 1968. He also taught at the University of California, Los Angeles (1974–1980), and Harvard University (1968–1974).

**JESUS CHRIST**

Jesus of Nazareth, one of the most influential humans in history, lives on as Jesus Christ. One-third of the human race, almost 2 billion people, identify with his name, calling themselves Christians. He is influential and believers identify with him because most of them see him as not merely human but as divine, whether as “Son of God” or in some other way uniquely bearing divine nature. Beyond the circle of believers as well as within it, many admire him, cite him, and seek to apply his teachings—especially about love—in human affairs apart from what most Christians claim about his divine character or his deity.

This fame and acclaim are astonishing, given the humbleness of his circumstances, the obscurity of origins and details about his life, and the arguments from the beginning about the meaning of his ministry and his character as being both human and divine. As for the circumstances, he was born to Mary, a young woman of Nazareth in Galilee, probably from four to six years “before Christ.” That confusing calendar reference results from adjustments in chronology made in more modern times. The period found Israel, which was conceived—also by Jesus—to be God’s special people, under the rule of
Romans, to whom they grudgingly paid taxes and against whom there were occasional revolts. Jesus himself came to be regarded as suspicious both by Jewish authorities in religion and in their relations to the Roman rulers as well as to the Romans themselves. In the mixture of loyalties and disloyalties, Jesus was executed by crucifixion. His dispersed followers regathered instantly, convinced that he was risen from the dead and that many among them had "seen the Lord" after his death. Forty days later they witnessed his Ascension and adored him as one who, in the words of the best-known Christian creed, "sits at the right-hand of his Father" in heaven and as invisible ruler of the world.

THE GOSPEL ACCOUNTS OF JESUS

Historians know this information not because a single Roman or Jewish historian left a record of any sort before Jesus’ death, but because stories cherished by Jesus’ immediate followers, quotations of his sayings and parables, and ponderings of the meaning of his divine and human character inspired his followers, or disciples, to produce four documents called “gospels,” which were transmissions of “good news” about him. Three of them, called Matthew, Mark, and Luke, were edited into the forms contained in the modern Bible, probably a generation after his death. The authors or editors of these had slightly different intentions, depending upon whether they wanted to attract Jewish or Gentile readers, or for some other purpose. Yet, for all their variations and despite some conflicts in their accounts, overall they present a coherent portrait. The Fourth Gospel, called John, may have come around the end of the first century of the Common Era, and includes more reflection on the meaning of Jesus’ words and works. In the centuries that followed, numbers of other “gospels” appeared. While some of them have advocates in the twenty-first century, none of them were accepted into the canon, the authorized collection called the New Testament that was approved by church leaders in the second and third centuries.

THE REFLECTION OF JESUS IN THE LETTERS OF PAUL

Before the gospels appeared, however, reflection on Jesus, now called “the Christ,” which meant “the anointed one of God” who had been foreseen and promised in the Hebrew Scriptures—the “Messiah” whom devout Jews still await—was developed and spread most notably by Saul of Tarsus, called Paul the Apostle after his own conversion. In his letters collected in the New Testament and in stories within the book of Acts, which can be seen as “Volume Two” after Luke’s Gospel as “Volume One,” Paul describes himself as a persecutor of Christian believers until he had an ecstatic experience of Jesus, who called him to a new vocation. Paul’s letters make very few references to the life of Jesus as it is described in the Gospels, but they concentrate on the meaning of his death and resurrection. In such writings Jesus is no longer the rabbi, healer, and wonder-worker of Nazareth so much as the risen and exalted Lord of all creation. Through faith in the divine grace God gave to believers in Jesus the crucified and self-sacrificial Savior from sin and divine condemnation, these believers are gathered as a kind of mystical “Body of Christ” and are to be raised from the dead as he was.

The understandings of who Jesus was were vastly diverse. President Thomas Jefferson, almost eighteen hundred years after Jesus’ death, despised the assertions and beliefs about Jesus the miracle-maker and exalted divine Lord. Like so many other advocates of the Enlightenment in his century and many admirers of Jesus in the twenty-first century, he wanted to rescue Jesus from the priests and to see him as the greatest exemplar of love and teacher of justice. At the opposite extreme there have been through all of Christian history movements that can be classified as “docetic,” for in their vision Jesus only appeared to be a mortal. Attempts to reconcile the extremes, represented already in the first Christian centuries by those who stressed his “human nature” versus those who overstressed the divine nature, became the preoccupying agenda item for a series of church councils, whose influence extended from the fourth century into modern times and into Christian discourse and teaching on all continents.

THE SPREAD OF WITNESS TO JESUS

As for these councils: According to the book of Acts and the New Testament letters of Paul, Jewish religious authorities in Jerusalem and Roman rulers there and elsewhere began to persecute followers of Jesus. Some saw them as subversive of Jewish temple practices and others as threats to Roman rule throughout the Empire. Very soon after Jesus’ death and resurrection, according to the book of Acts, a witness named Stephen was stoned to death in Jerusalem. According to tradition, in 64 CE both Paul and a leading disciple named Peter were executed in Rome. While many followers of Jesus in these times were basically nonpolitical, they refused to engage in simple acts of what to them looked like betrayals of Jesus, such as offering a pinch of incense on the emperor’s shrine, the emperors then being conceived themselves as somehow divine.

The boldness of the apostles, as early articulators and witnesses were called, and then the readiness of their followers to face whatever the authorities threatened because of their faith in Jesus, only added luster to his reputation.
and served to attract ever more followers. By the second century followers of Jesus, called not “Jesusians” or “Jesusists” but “Christians,” were spreading north and east beyond Antioch into present-day Syria and through Asia Minor, present-day Turkey. Early strongholds of belief in Jesus were in northern Africa, where notable “church fathers” held sway. In both Asia and Africa some followers took the call of Jesus to mean denial of the pleasures of the world, and went to the desert and other remote places, there in isolation of community to become monks. They pioneered in a practice that through the twenty centuries had led to special devotion to Jesus and self-sacrifice in his honor and following his commands.

Those commands, however, took their impetus from Gospel records that embody and impart some apparently contradictory impulses and commands. On one hand, the Gospel writers remember Jesus calling for drastic self-renunciation. Followers were to deny themselves, take up their cross—a reference to the mode of his death by crucifixion—and even to desert their families and familial obligations.

On the other hand, and just as emphatically, the Gospel writers depict Jesus as enjoying life and teaching others to do the same. His special form of discourse was in parables, short stories that usually included a kind of overturning of conventional ways of looking at reality. It has been said that one will not understand these preserved parables without recognizing that they turn everything topsy-turvy. The proud and powerful and respectable will be dumped and debased, while the humble and weak and outcast will be privileged in what Jesus announced as “the Kingdom of God.” Kingdom of God did not mean an early reign, since the Gospels have him saying that his kingdom was not of this world, but instead focused on the sovereign saving activity of God manifested in Jesus who was in their midst. So “the last will be first” and the first last; no one could enter the kingdom, he had said, unless they changed and became “like a little child;” the lost sheep matters more than those at home in the flock. More shockingly, Jesus favored the company at table of prostitutes, the hated tax collectors, and others seen as marginal or outcast by respectable people.

JESUS ON JUSTICE AND LOVE

The Gospel portraits show Jesus as both an announcer of God’s justice and imparter of God’s love. As for justice, a series of sayings preserved as the Sermon on the Mount or, in another gospel, the Sermon on the Plain, called for radical adherence to the call of God to effect justice in the world. The discourse combines such stern language with words of blessing and comfort, sayings followers have cherished through the centuries. These announce that “blessed are” the peacemakers and those who hunger and thirst after righteousness.

It is not likely that Jesus would have remained such a powerful and attractive force to all conditions and sorts of people, from those in royal courts to those falsely imprisoned or abandoned by others, were it not for the Gospels’ portraits and preserved sayings about love. Jesus in these accounts showed extreme devotion to the law of God, also as it was believed to be condensed in the Ten Commandments and in many other laws preserved in the Hebrew Scriptures and declared as applicable in Jesus’ own time. He was even more extreme in declaring that this Law of God had its limits in the face of human need. He saw the value of the Sabbath, the divinely commanded day of rest, yet when his disciples were desperately hungry he allowed them to prepare grain for food, and when someone needed healing, he healed, scorning those who invoked the Law of God over the call to love. He was particularly confrontational when he faced religious authorities that overlooked human need in the name of their interpretations of divine commands. When asked to summarize all the commandments he drew them down to two: the love of God and the love of neighbors, or others. Every serious return to the teachings of Jesus focuses on both the seriousness of his demands for justice and the abundance of his calls to love, the love that followers saw in his giving of himself to death.

JESUS IN PRAYER AND DOCTRINE

To believing Christians in all cultures, Jesus is not merely an historical figure, written about and admired after twenty centuries. Most of them regard him as a living presence. The Gospels hear him saying that when two or three followers are gathered in his name, he is there among them, so they regularly worship in his name. Some pray to him, but the main interest for Christians is to pray through him, following his word that they are to approach God, the one he called “Abba,” an endearing word for “Father,” in his name. Catholic Christianity in many denominational forms is sacramental, and its adherents believe that Jesus is especially present among them in the sacred meal described in the Gospels as occurring first the night before he was killed and which he commanded that they should repeat.

Second, Jesus has been present in visual representations. No one knows what he looked like, and in all societies and cultures artists portray him as an ideal figure in their own. In the Eastern Orthodox churches he appears in very formal guise in icons. In Latin (in Europe, in Spanish cultures; in the Western Hemisphere, in Latin American cultures), he is usually portrayed as a whipped, bleeding sufferer on the cross. In other cultures he is
domesticated and portrayed as a kind of bourgeois com-
forter of children and quiet teacher.

Third, Jesus lives on in doctrine or dogma. While the
gospels show him uninterested in abstractions and distant
formulations, it was natural that as Hebrew-speak-
ing Jewish followers of Jesus moved into the larger culture
today called “Greco-Roman”—the Gospels about Jesus
and other speakers of Aramaic and Hebrew were them-
selves written in common Greek—teachers found it
important to define how Jesus differed from others for
whom divine claims were made. They had to show how he
related to his divine Father and, since the New Testament
writings made much of this, to the Holy Spirit. In the
early church councils leaders combined Hebrew biblical
testimony and simple stories with Greek philosophical
themes. They had to show how to make sense in their
world of their belief that the human Jesus was also the
exalted Lord. They were pressed to show to Jews and oth-
ers that and how they were monotheists, believers in one
God, and not in two or, with the Holy Spirit, in three.
Out of this grew the doctrine of the divine Trinity, in
which Jesus is “of one being” with the Father and is also a
true human.

JESUS IN SOCIETY AND POLITICS

Those interested in the social sciences—history, sociology,
and political science—may be aware of the other three
modes but they also study how devotion to Jesus inspires
ethical response among those who want to be numbered
as his followers. They pay attention to the movements and
church bodies that exist because of the desire by believers
to respond to his calls and promises. In his name leaders
helped guide the persecuted believers to situations of
power. After Constantine in the fourth century, both in
the Roman West and the “Constatinopolitan” East, Jesus,
as represented by bishops and other church leaders, shared
earthly power with emperors and magistrates. The name
of Jesus was invoked by his followers against their and,
they believed, his enemies. His cross appeared on the ban-
ers of Crusaders who more than a thousand years after
Jesus lived as someone to be relied on and invoked by those
who are troubled, ill, or dying. If these invocations seem
far removed from those that see him as a ruler through
representatives on Earth, as the leader of “Christian sol-
diers, marching as to war,” the anticipations of both are
present in the writings of Paul, the portraits of the Gospel,
and the many efforts through the ages by believers to
come to terms with someone they believe is obviously
human and, in faith, adored and often followed as divine.

JEWISH DIASPORA

Diasporas in general and the Jewish Diaspora in particu-
lar are very important complex sociopolitical entities that
are playing a growing role in most states worldwide, as
well as in regional, international and transnational poli-
tics. The diaspora phenomenon, including the Jewish
Diaspora, is an expanding field of study.

Many people worldwide, including scholars—espe-
cially those adhering to the instrumentalist and construc-
tivist approaches to the origins and development of ethnic
groups, nations, and diasporas—consider the Jewish
Diaspora as a “modern or even a postmodern pheno-
menon. While it is true that the period since the mid-
nineteenth century has seen a marked change in the
entire diasporic phenomenon—including the Jewish
Diaspora—the Jewish Diaspora, like other ancient diaspo-
ras, has maintained many of its “old” characteristics.

THE HISTORY OF THE JEWISH
DIASPORA

The Jewish Diaspora was established as a result of both
voluntary and forced migrations of Jews out of their
ancient homeland—Eretz Israel (the Land of Israel). Later,
Jews were either exiled from their host countries
(such as Spain and England in the Middle Ages and
Middle Eastern states in the twentieth century) or volun-
tarily migrated to secondary and tertiary host countries.
The forced and voluntary migrations that resulted in the
establishment of the Diaspora began much earlier than
what has been regarded as the “official” date of the
Diaspora’s establishment, that is, the creation of the Jewish Diaspora in Babylon.

Return movements of Hebrews from Egypt (the Exodus) and other Middle Eastern countries to the Land of Israel have occurred throughout antiquity and the Middle Ages. Nevertheless, Jewish communities continued to exist in these countries after such return migrations. Hence, a Jewish Diaspora has persisted since antiquity.

The expulsion of the Israelites by the Assyrians and of the Judeans by the Babylonians only added new larger groups to the already-existing Jewish diasporic communities in various parts of the Middle East. This means that after the initial establishment of the Jewish diasporic entities in Egypt and Syria, new Jewish diasporic entities were established in various parts of the Middle East and Asia Minor and later in the Balkans. The Babylonian Jewish Diaspora served as a model because the Jews created there an “autonomous diasporic sociopolitical system,” in which the Diaspora, rather than the devastated homeland, became the national center and played the crucial role in the nation’s persistence, cultural development, and political influence.

The establishments of the Greek Empire and later the Roman Empire, both of which controlled vast territories, facilitated both the permanent settlement of Jews and the establishment of communities in various parts of these empires and the communication between the various dispersed Jewish communities.

This expansionist trend continued during most of the Middle Ages. The Jewish Diaspora spread from the eastern Middle East, Greece, and Rome to North Africa, Europe, and Asia. Later, partly voluntarily and partly because of anti-Semitism, anti-Jewishness, and hatred, Jews migrated and established diasporic entities in South and Latin America, and then they moved to the United States, Canada, Australia, and South Africa. In fact, the center did not shift back to the homeland even when the regional geopolitical situation changed.

MORE RECENT DEVELOPMENTS

The Zionist Movement, which advocated the return to Palestine and the establishment of a Jewish independent state there, was established toward the end of the nineteenth century and during the early twentieth century. Because of growing temptations of assimilation and of integration into democratizing and secularizing host lands, on the one hand, and because of persecution, anti-Semitism, and pogroms, on the other hand, the most urgent problem then facing Jewry was how to prevent defection of individuals and groups from Judaism and from membership in the Diaspora’s communities. Thus, already at that historical juncture, the problem was how to ensure continuity and enhance the readiness of Jews to identify as such, as a basis for a solidarity that could enable Jewish diasporic joint action.

Partly because of the Diaspora’s geographic dispersion and partly because of ideological pluralism among Diaspora Jews, it was difficult to reach consensus about the preferable strategy for the nation’s survival and persistence. Hence, during the late nineteenth and early twentieth centuries there emerged various approaches to these questions, and virtually all shades of strategies gained adherents. These included assimilation, integration, participation in class struggle (namely, adopting the socialist and social-democratic solutions), cultural and political autonomy, and corporatism, the latter of which meant formal representation of the Jewish community vis-à-vis host governments, such as in Great Britain.

During this period, the main new facet was the birth of the separatist Zionist movement’s strategy, which called for the Jews’ return to Palestine and the reestablishment there of their own sovereign state.

Prior to World War II (1939–1945), the emerging but small Zionist movement faced tough intranational competition with other Jewish movements that had emerged in the Diaspora. Actually, prior to the emergence of Nazism and World War II, Zionism was a marginal movement in world Jewry, and its strategy did not attract the majority of Jews. The impact of that war, especially the painful realization of the full scope of the Holocaust and its disastrous consequences, created the right backdrop for a breakthrough by the Zionist movement. Many Diaspora Jews realized that the Zionist strategy was not only feasible but also an appealing solution to the problem of Jewish survival and national revival. Though the situation was ripe for the implementation of the Zionist strategy, membership in and support of the Zionist movement was still rather limited.

DEBATES ABOUT FUNDAMENTALS

The efforts to form consensus around the Zionist solution generated many delicate questions about central issues, some of which are still debated in the early twenty-first century. Among these, an important issue has been what should be the relations between the Zionists and other Jewish groups that opted for other strategies. Another unsolved issue revolves around reconciling the various elements in the national identity and perceptions. Because this fundamental question has not been solved, the issues of the principles that determine Israeli citizenship, and consequently the relations between Israel and certain segments in the Diaspora, have remained unsolved.

An additional debate about essentials that has not been concluded concerns the centrality of Israel versus the autonomy of diasporic communities. In two large and
strong diasporic communities—the U.S. and French communities—strong inclinations toward cultural and political self-sufficiency and freedom of action have emerged vis-à-vis Israel. Connected to these trends, new attitudes have emerged concerning certain practical issues, such as loyalty to Israel versus host countries, and Israel’s “right” to influence Diaspora leaders and members in order to increase support for its endeavors.

Furthermore, there was and there still is no consensus between Diaspora and Israeli leaders concerning the role of the Diaspora in the establishment of the Israeli state. In the wake of World War II, this historical act was promoted and actually implemented by leaders and parties adopting an ideology that emphasized the predominance of the Yishuv (the Jewish community in Palestine) in the Jewish nation.

After the Holocaust, when the Jews still constituted a stateless diaspora, large segments in various Jewish communities adopted an exceptionally supportive strategy toward the Jewish state. Later this strategy changed. In most Western democracies, where Jewish communities have been able to act relatively freely, these entities have adopted a communal strategy. Essentially, this strategy means not only moderate social, political, and economic behavior, but it also has determined the nature of the organizations the Diaspora operates. On a spectrum of strategies that runs from an assimilationist poll, on the one hand, to a return to the homeland, on the other hand, the communal strategy is regarded as one that poses major threats neither to the host countries nor to the members of the Diaspora. By adopting this strategy the Diaspora members implicitly pronounce that they accept the main social, political, and economic rules of the game in the host countries and that only under extreme circumstances would they adopt dual loyalties. When fully implemented, this pattern diminishes potential and actual controversies and clashes between the Diaspora and its host lands.

THE EFFECTS OF THE ESTABLISHMENT OF THE STATE OF ISRAEL

The establishment of Israel in 1948 marked a fundamental change in the position of the Jewish Diaspora. Whereas prior to its establishment the Jews constituted a “classical stateless diaspora,” afterward the Jews dwelling outside Israel should be regarded as a “classical state-based diaspora.” Since 1948 the Jewish Diaspora has shown great similarity to other classical diasporas whose connections are with independent homelands.

After the establishment of Israel a new group joined the classical Jewish Diaspora—Israeli emigrants. Most of these Israelis emigrated to and settled in various host countries as a result of voluntary decisions, and therefore they also hardly regard their situation as exilic.

The Land of Israel is a crucial element in the ethno-national-religious identity of Diaspora Jews. Throughout history the collective memories of the homeland remained vivid in the hearts and minds of Diaspora Jews. The spiritual and emotional ties of Jews, though not all Jews, to the ancient homeland contributed to a sense of national solidarity. Later this solidarity also served as a basis for various activities on behalf of that segment of the nation that dwelled in the homeland. Such support peaked in the wake of the establishment of modern Israel, and still later during and after the 1967 and 1973 wars. Since then general support for the Jewish state has been declining.

Similar to the situation with all other diasporas, the Jews form a majority only in Israel, and only small minorities in all their host countries. In fact, the majority of the nation dwells outside the homeland—most of them in relative security, economic prosperity, and cultural bloom. These facts and Israel’s problematic security situation have raised the issue of the location of the national center, and of its corollary, the question of peripherality in this nation. During the first two decades after the establishment of Israel it seemed as if the Diaspora recognized the new nation-state as the main Jewish center, and its policies and actions determined developments in the Diaspora.

By the early twenty-first century, there were at the least four major Jewish centers—the American, French, Russian, and Israeli. Among these centers there is implicit and explicit, continuous tacit competition about predominance in the entire nation.

In most of the host countries, especially the United States, Canada, Great Britain, France, Australia, Mexico, and Peru, there are relatively large groups of core Jews who have well integrated into these societies, political systems, and economies. These Jews—most of whom were in their forties and fifties in the early twenty-first century—obtained an academic education and became affluent. Many of the members of these well-integrated groups are in high-tech fields, academia, and other professional occupations, such as journalism, medicine, banking, insurance, and law. Some of them belong to the richer segments in these countries, but most of the members of these groups belong to the middle and upper-middle class. The main reasons for these achievements are: Jews’ determination to continue to survive and overcome actual and perceived difficulties in their host lands, their painful memories of historical deprivation and persecution, family and communal support and encouragement, a strong emphasis on education within their families and communities (education being a precondition for economic success), and the existence of Jewish communal and international networks and systems of communication.
Jewish Diaspora

There are, however, still many Jews permanently residing in the above-mentioned and other host lands, such as east and central European and some Latin and South American countries. These Jews are typically older and belong to lower income groups or to the working class. These poorer Jews need support from their host governments and their Jewish communities. This last factor affects the allocation of the resources that are at the disposal of the various Jewish diasporic communities. When the political and economic conditions in such host lands become more difficult, such Jews get support from the wealthier Jewish communities. This has been the case, for example, with the Jewish refugees created by World War II, with Jews in Middle Eastern and North African countries until the 1950s, and, more recently, with Ethiopian Jews.

By the early twenty-first century, the return of Jews to countries where they were persecuted and from which they were expelled had also become apparent. The “return” of Jews to host countries such as Germany, Spain, and Austria, shows that Israel is not regarded as the undisputed national center. Moreover, the majority of Diaspora Jews has stayed and will be staying in their host countries.

Despite persecution and migration to secondary and tertiary host countries, on the one hand, and acceptance by host societies and governments that result in assimilation or full integration, on the other hand, in various host countries a Diaspora core is maintained. These cores of devout Jews maintain their ethnonational and religious identity and resist assimilation or full integration.

In the past, the religious element in the Jewish identity was essential for the entire nation. Since World War II, however, this element has lost some of its significance. Though religious Jews claim that they constitute the main barrier against a sweeping assimilation that would result in the disappearance of Jewry, the ethnonational factor now serves as the basis for the continuous existence of many Jewish communities all over the world.

THE COMPARATIVE PERSPECTIVE

Because of its origins, endurance, and attachment to its ancient homeland, it is not surprising that the Jewish Diaspora has been considered an imperishable “classical,” “archetypal,” and “mobilized” diaspora. Some observers, however, are pessimistic about its future survival. The gist of the pessimists’ argument is that the new pluralism, multiculturalism, and tolerance toward the “others,” which prevail in the more democratic host countries, speed up the assimilatory tendencies that demographically decimate world Jewry.

This diaspora should now be regarded as an ethnonational–religious state–linked diaspora that is similar to other older and newer existing diasporas. In fact, the Jewish Diaspora fits a collective profile of ethnonational diasporas (Cohen 1997; Sheffer 2006). As applied to the Jewish case, the profile includes a number of elements.

As has been shown in the historical analysis above, the Jewish Diaspora was created as a result of voluntary and forced migration out of its homeland—Eretz Israel—and out of other host countries, and eventually as a result of its members’ permanent settlement in host countries. This diaspora has remained a rather small minority in all its host lands; after permanently settling in their host lands, the Diaspora’s members have maintained their ethnonational identity. This identity is buttressed by strong religious beliefs. The identity of this entity’s members is based on a combination of nonessentialist-primordial, psychological, and instrumental factors. The nonessentialist-primordial factors include the idea of common ancestry, biological connections, a common historical language, collective historical memories—among which the twentieth-century Holocaust is important—a discernable degree of national solidarity, a deeply rooted connection to the ancient homeland, and similar patterns of collective behavior. This identity is also based on instrumental factors concerning various benefits that derive from being members of the Diaspora. The strategy of many Jewish diasporic entities is communalist and is implemented through multiple organizations and active trans-state networks that protect and promote the diaspora’s political and economic interests. Another element of the profile is that most members of the Diaspora do not regard their existence in their host countries as exilic.

On the basis of such identity and identification, a sense of solidarity emerged and has been sustained. Such solidarity has facilitated continuous connections between the elites and active members on the grassroots level, which pertain to the cultural, social, economic, and political matters of the entire entity. In turn, these constitute determining factors in the relations among Jewish diasporans, their host countries, their homeland, their brethren in other host lands, and other international actors.

All the above-mentioned factors serve as the bases for organization and collective action. An essential purpose of these organizations and activities is to ensure the Diaspora’s capability to survive and to promote its interests in host lands and in the homeland, as well as to maintain cultural, social, economic, and political connections with the homeland and with other segments of the same nation.

Wherever and whenever they are free to choose, Jewish diasporans tend to adopt distinct strategies concerning their existence in their host lands and with their homeland. Generally, core members of the Jewish Diaspora adopt the communalist strategy, which is intended to ensure integration, rather than assimilation,
in the host countries. This strategy, coupled with the wish to maintain contacts with the homeland determines the nature of the organizations that the Diaspora establishes, and also leads them to establish elaborate and labyrinthine trans-state networks.

The establishment of the Diaspora’s organizations, including the trans-state networks, and their subsequent activities, raises complex issues of loyalty. To avoid and prevent undesirable clashes between the Diaspora and its host societies and governments concerning the laws of the land and the norms of the dominant segments in the host societies, the Diaspora’s members usually accept these norms and comply with the laws. Nevertheless, during certain periods, especially when the homeland or the host country finds themselves in the midst of crises, or when the Diaspora encounters severe difficulties, certain segments in the host societies develop negative attitudes about the Diaspora’s disloyalty. On certain occasions, such tensions and clashes lead to the homeland’s intervention on behalf of its Diaspora or meddling in its affairs.

As noted above, despite certain pessimistic predictions of the demise of this ancient diaspora, all indicators show that like other similar diasporas, the Jewish Diaspora will continue to exist and even prosper.

JEWS

According to the Torah, the history of the Jewish people begins with a call to the patriarch Abraham to abandon his ancestors’ idol worship and to “Get thee out from thy country … unto the land that I will show thee” (Gen. 22:1). Jewish history and identity, as recounted within the people’s own tradition, thus begin with a command, a renunciation, and a departure. The Torah also recounts the earliest Jewish generations’ experience of exile in Egypt, followed by the miraculous deliverance, return, and reconquest of that divinely promised land. However, current archaeological consensus is unable to agree on confirmation of key moments in the biblical account.

The name Jew and its various cognates (e.g., French Juif, German Jude, Arabic yahud) all stem from the name Judah, the ancient kingdom that shared the name of one of the twelve sons of the biblical patriarch Jacob. Other names for the group are Hebrew (generally referring to the ancient period, but also the name of the main ethnic language) and Israel (a name of Jacob in the Bible and also the name of the second ancient Jewish kingdom).

REASONS FOR AND LOCATIONS OF THE ORIGINAL DIASPORA

Jews are known simultaneously for their lasting devotion to their homeland (Israel, Zion, Palestine, or simply “the Land”) between the eastern shore of the Mediterranean and the Jordan River, and for their long endurance in conditions of diaspora or exile. The main historical exiles of ancient Jewry followed the destruction in 586 BCE, by the Babylonians, of the ritual center in Jerusalem known today as the First Temple, and then the destruction in 70 CE, by the Romans, of the Second Temple. However, Jewish diaspora—the existence of stable and persistent Jewish communities outside the historical homeland—long predates the loss of the ritual center and of Jewish sovereignty. The ancient Jewish community of Alexandria, with its rich Hellenic culture and regular remission of tribute to Jerusalem, is only the most dramatic example of such a pre-exilic diaspora.

Babylonia quickly became a key and powerful center of ancient Jewish life, throughout the entire Second Temple period and beyond. In the wake of the Roman exile, groups of religious leaders collectively known to current scholarship as “the Rabbis” devoted generations to the elaboration and transmission of the Oral Torah, eventually redacted into the texts known as the Mishnah, and in the commentaries on the Mishnah known respectively as the Babylonian Talmud and the Jerusalem or “Palestinian” Talmud. Rabbinic Judaism was a minority formation in its earliest centuries (outnumbered by what is broadly known as Hellenic Judaism and by other rival formations, eventually including its only surviving rival,
known as Karaite Judaism). Despite continuing sentimental attachment to the ancient homeland, the Babylonian Talmud retained far more central authority than its Jerusalem rival. The Rabbinic models of scriptural interpretation, legal adaptation, and substitution of prayer for Temple ritual came to serve as the fundamental template for Jewish communal life throughout various diasporas until the modern period.

BASIC RELIGIOUS BELIEFS AND PRACTICES

The notion of “chosenness” is understood in Jewish tradition in terms of obligation and reward. The Book of Deuteronomy recounts the Hebrew nation’s reaffirmation of God’s original covenant with Abraham; the people will keep God’s “statutes” and “commandments” and “ordinances,” and God will in turn keep them as “His own treasure” (am segula) (Deut. 26:16–18). Various examples of the literary genre of commentary known as midrash recount God’s prior offer of the Torah to other nations, each of which is unable to accept one of its major premises and thus refuses to enter into the divine covenant.

Though this deity is sometimes referred to as “the God of our ancestors” or “the God of Israel,” the biblical narrative—and especially the Prophetic writings—reflect the conviction that, as the creator of all being and of all humanity, this divinity’s sphere of power and interest is not limited to one nation or territory. Moreover, in sharp contrast to some other national epics, the origin of the people in human history is separated from the original creation of the earth and its creatures. Accordingly, Jewish tradition and rhetoric view the non-Jewish “other” through a range of metaphorical frameworks: as “cousins,” descended through a mythic genealogy from the common human ancestors Adam and Eve; as instruments of a divine plan centrally dependent on the covenant and on the Jews’ always inadequate performance thereof; and occasionally as creatures equally precious in the sight of God: “Are ye not as the children of the Ethiopians unto Me, saith the Lord?” (Amos 9:7).

At the ideological plane, diaspora Jewish life has been played out in this continuing and productive tension between ethnocentrism and universalism. The synagogue, wherever it is, becomes a form of mikdash me’at, a “miniature” substitute for the lost Temple in Jerusalem. The study of the forms of Temple worship and recitation of the order of sacrifices both recall ancient sovereignty and give form to dreams of messianic restoration. The study of sacred texts transcends mere recitation through a chain of commentaries that both preserve understandings and distort them to make the authorities fit new circumstances. The Rabbinic academies (yeshivot) of ancient Babylonia come to serve as models for the new academies in eastern Europe devoted to the defense and reinvention of Talmud study in response to modern forms of knowledge and inquiry.

Practice—the meticulous and highly rationalized observance of positive commandments and prohibitions—is central to the conduct of a traditionally Jewish life. Laws of separation and purity (such as dietary limitations, bans on the mixing of certain species in agriculture, and menstrual taboos) both help to order the social world and sustain the larger lifeworld separation distinguishing Jews from non-Jews. During the period of Jewish sovereignty, many of these laws served to underscore the special sacredness of the land itself. In diaspora, their function in preventing the dissolution of the Jews as a kin and ideological group become more salient.

Jewish law and custom are all highly androcentric, though not univocally so. They are heteronormative, though they do not reflect the gender structures of the post-Enlightenment European bourgeoisie, from the perspective of which the Rabbinic ideal of the quiet, studious, “tent-dwelling” Jacob may even seem effeminate (see Boyarin 2004). Men under traditional Jewish law exclusively enjoy various rights and powers, such as serving as witnesses, as members of prayer quorums, and as the initiators of divorce. Apologetic accounts stress the key role of women in the family, but at various points women in Jewish communities have also held important economic roles, and the Talmud also makes clear the rights of women as property holders and contracting parties in ancient Babylonia.

Since the Prophetic response to the nation’s demoralization in the wake of the first and second exiles, the messianic promise of ultimate redemption and restoration—sometimes accompanied by visions of universal peace and well-being—has been a core tenet of Jewish belief, ritual, and culture. Messianism has also been a central motivating theme of the powerful and continuing tradition of Jewish mysticism, which has sometimes coexisted with and sometimes contended with Rabbinic textualism. Some leading scholars have argued that Jewish messianism is distinctly characterized by the expectation of the advent of the messiah as a historical and public event, over and against ideologies of individual redemption.

JEWISHNESS AND ITS OTHERS

Since earliest times, and including periods of state sovereignty, the Jewish collective has often found itself either a client of or in conflict with larger powers. Much Prophetic discourse turns on the geopolitical dilemma of choosing between loyalty to the rival empires of Assyria and Egypt. The biblical narrative of enslavement and deliverance turns on an image of the Egyptians as heartless and
The destruction of the Second Temple resulted in large part from Jewish resistance to incorporation within the Roman provincial administrative system. Christianity was an outgrowth of certain messianic trends among Jews, and there has been growing scholarly acknowledgment in recent years not only of the significance of Jesus’ Jewishness, but the continued Jewishness of many of the first “Christians,” including Paul. Yet Christianity became radically distinguished from, and powerfully opposed to, Judaism and Jewishness once it became the state religion of the Roman Empire. Similarly, Islam arose in Arabia in a social milieu where Jews were a prominent part of the mix, yet the rejection of Muhammad’s (c. 570–632) message by the local Jewish community gave rise to strains in Islam that are at best ambivalent toward Jews and at worst overtly hostile.

ENGAGEMENT IN WORLD CIVILIZATION

Jewish communities eventually spread (or were established by conversion) throughout the circum-Mediterranean region, Central Asia, and eastern and western Europe. With the exception of sub-Saharan Africa and much of East Asia (there were smaller Jewish communities for centuries in India and China), Jews were thus found throughout the Old World. Throughout the medieval and early modern periods, Jews played prominent roles in the world system of trade and communication that stretched from the Atlantic coast of Europe through the Mediterranean and into Asia, and for centuries, Jewish communities were concentrated in Islamic lands, ranging from Iberia through North Africa and the Middle East. Yet that world system was unstable, and Crusader anti-Muslim zeal sometimes spilled over into murderous anti-Jewish violence.

During the High Middle Ages, in a complex process tied to the formation of nascent nation-states, long-established Jewish communities were forced out of various parts of western Europe; many of their number migrated to regions in eastern Europe that were then being colonized by Christian nobility, peasants, and clergy. More than a century of forced conversions and persecutions culminated in the expulsion of Jews from Iberia at the end of the fifteenth century. While this ended centuries of fruitful and conflicted multireligious contact that had produced Jewish luminaries such as Moses Maimonides (1135–1204), Abraham Ibn Ezra (1092–1167), and Solomon Ibn Gabirol (c. 1021–1058), it also gave rise to new, flourishing, and influential communities across the Ottoman Empire, known as Sephardim and speaking the Judeo-Spanish language of Ladino. However, a dramatic rise in the Jewish population of eastern Europe during the nineteenth century radically shifted the “center of gravity” of Jewish communities in the modern period.

THREATS AND SOLUTIONS TO EXISTENCE IN MODERNITY

Modern European nationalism, the rise of democratic citizenship, and Enlightenment ideologies of individual autonomy and of freedom of conscience all presented both dangers and opportunities for Jews and Jewishness. Distinctive legal status—both limitations and protections—for Jews began to crumble. In western Europe, the National Assembly during the French Revolution of 1789 heralded the abolition of autonomous Jewish communities with the famous phrase, “To the Jews as a nation, nothing; to Jews as individuals, everything.” In modernizing Germany, Jews were prominent in literature, science, and the arts, though they continued to suffer social and institutional discrimination. In the Russian Empire, “the prisonhouse of nations,” Jewish communities faced a bewildering and inconsistent sequence and array of liberalizing gestures, increasing restrictions on settlement and occupations, and forced assimilation in the guise of modernization. Individual Jews and Jewish movements (notably the Jewish Workers’ Bund in Russia, Poland, and Lithuania) were prominent in socialist and revolutionary efforts to overthrow the czarist regime. Jews were full participants in colonial, democratic, and capitalist ventures in the New World, and the United States became a center of Jewish population and creativity.

Perhaps fueled by the dramatic encounter between traditional Jewish communities and the new bourgeois sphere, thinkers of Jewish origin such as Karl Marx (1818–1883), Sigmund Freud (1856–1939), and Émile Durkheim (1858–1917) were pioneers in the reflexive articulation of modernity’s self-understanding, while Jewish writers, scientists, and musicians likewise made disproportionate contributions to modern culture. The haskalah or “Jewish enlightenment” stimulated a new, secular Hebrew literature, as well as a modern Yiddish literature, much of which has stood the test of generations as a commentary both on the limitations of tradition and on the frequently empty pretensions of the new.

Yet Jewishness and the Jews were frequently seen as a “problem” for Western modernity, whether because their potential loyalty and capacity for absorption as fellow citizens of secular nation-states was in question, or because the organizing logic of those nation-states rested in unacknowledged ways on assumptions of their constituents’ shared Christian heritage. One reaction was the crystallization of Zionism as the Jews’ own modern nationalist movement, which eventually took material form in the effort to convince Jews to migrate to Palestine and to create the infrastructure for Jewish state sovereignty there to
be renewed after nearly two millennia. Zionism bears in turn a complex relation to traditional Jewishness, rejecting as neurotic substitutions much of the diasporic forms of Jewish life, while mobilizing the memory and longing for the lost homeland that have nourished Jewish sensibilities in exile.

Political engagement by Jews in liberal and socialist struggles throughout the West helped fuel the modern anti-Semitic movement. Anti-Semitism was itself a reactionary response to the rapid pace of social and economic change, paradoxically bolstered by modern theories of biologically determined and hence immutable racial characteristics. During the 1930s, a time when Western economy and society were simultaneously resisting workers’ revolution and reeling from catastrophic disruption to the capitalist economy, Jews were irrationally but opportunistically tarred as the bête noire of the imagined “Aryan” race. The consequent call to eliminate the Jews, originally a demand for expulsion, was transformed in the course of World War II (1939–1945) into an active program of genocide. There were an estimated 18,000,000 Jews at the beginning of that war; by its end, a third of them had been slaughtered.

PRESENT SITUATION

The map of the Jewish world has been dramatically reshaped in past centuries, as a result of genocide, assimilation, migration, nation-building, and renewal. The Jews of the world are far less widely dispersed than they once were, and much has been lost. The State of Israel explicitly defines itself as a Jewish state, yet along with a significant Arab minority, its population includes numbers of immigrants whose “Jewish” status according to religious law has been hotly debated. Moreover, Israel and its Jewish population continue to face vital issues of cultural and political integration into the Middle East.

Along with Israel, the United States holds by far the world’s largest Jewish population, and American Jews are generally considered well integrated. Markers of Jewish identity and culture are readily present and celebrated in media and popular culture. Those concerned with Jewish continuity worry about high rates of intermarriage among moderately affiliated Jews. There is an extraordinary range of options for expression of religious Judaism, for the explicit linkage of Jewishness to other nonmajoritarian identities, and for the preservation and reinvention of secular Jewish culture. Meanwhile, traditionalist religious communities have enjoyed a resurgence, experiencing high birthrates and close to universal retention of young people within their communities.

Outside of Israel and the United States, France retains the largest Jewish population, largely comprising North African immigrants and their descendants. French Jewry today stands as a test case for the continued viability of Jewish and indeed of minority communities more generally in contemporary western Europe, and some see its future as clouded by the appearance of a “new anti-Semitism” there. Significant Jewish populations also are found in the countries of the former Soviet Union, in Canada, in the United Kingdom, and in Argentina.

JIHAD

Jihad is an Arabic term meaning, as a noun, “struggle” or, as a verb, “to exert effort” toward a goal. The primary associations of the term are religious, specifically with reference to Islam. The Qur’an exhorts believers to struggle “in the path of God” or “to make God’s cause succeed” (8:39). Such struggle involves all of one’s power and resources, as one seeks to “command right and forbid wrong.” Under
In certain circumstances, jihad is identified with *qital*, meaning “fighting” or “killing”; indeed, in Islamic juridical discourse, this association is prevalent, so that in some contexts, jihad can be translated as “armed struggle.” In some contemporary writing by Muslims, the broader meaning of the term as “moral struggle” is stressed, and military associations are downplayed. Overall, it is best to keep in mind that the term occurs in connection with a view by which human responsibility is a matter of striving to bring all of life into a pattern of relationships consistent with God’s will. In some circumstances, the means appropriate to this struggle are military; in others, not.

Stories by which Muslims interpret the Qur’anic “verses on fighting” illustrate this way of construing the meanings of jihad. According to traditional dating, Muhammad’s call to prophecy occurred in the year 610 CE, and by 612 he began to preach or to “call” others to Islam. A small band of “companions” gathered around him. They met with hostility, even persecution from the people of Mecca, the Prophet’s home city. In this context, some of the companions urged the use of force, by way of retaliation for wrongs done to the believers, and to deter further persecution. Muhammad resisted, indicating that God’s orders only allowed him to preach.

By the year 622 (the year 1, in the Islamic calendar), things had changed. In that year, Muhammad received God’s order to immigrate to Medina, a city to the north. He also received permission to fight, specifically in terms of God’s provision for the protection of believers (Qur’an 22:39–40). Once in Medina, Muhammad functioned as head of state and military commander, all the while continuing to preach. Verses of the Qur’an that Muslims number among the “Medinan” texts indicate a growing sense that military action is not only permitted, but necessary, and finally obligatory in the campaign to establish a “zone of security” for the Islamic community. In his Farewell Sermon (630), Muhammad declared that “Arabia is now solidly for Islam,” meaning that the various tribes were now under Islamic governance.

In the years following Muhammad’s death, jihad came to be associated with the efforts of Muslims to extend the benefits of Islamic governance to people and territories beyond Arabia. A series of conquests “opened” most of the Middle East, and much of North Africa and Asia, to the influence of Islam. In this connection, the religious specialists called *ulama* developed a set of “judgments pertaining to jihad” that function as an Islamic “just war tradition.” Thus, jihad, in the sense of legitimate war, must be commanded by the officials of an Islamic state. It should be fought for the cause of God, meaning the expansion, establishment, or defense of Islamic territory. And it should be fought with right intention, in the sense of avoiding undue aggression. Fighters should avoid directly targeting noncombatants and, according to some authorities, they should further avoid the use of weapons or tactics that might bring about unacceptable levels of “indirect” damage to civilian life. The rules governing jihad were developed and recognized by specialists associated with the majority (Sunni) and minority (Shia) versions of Islam, though the latter insisted that jihad could only be authorized by a divinely authorized Imam or leader, the implication being that most wars fought in the name of Islam did not really qualify.

In the nineteenth and twentieth centuries, jihad came to be associated with Muslim resistance to European and North American imperialism. Some argued for military resistance, others for education designed to make Muslim economies competitive. Important examples of military jihad include uprisings led by Uthman Dan Fodio (1754–1817) in Nigeria and Muhammad Ahmad al-Mahdi (1884–1885) in Sudan. As for the educational approach, the development of Aligarh Muslim University in India by Sayyid Ahmad Khan (1817–1898) and the campaign for educational reform in Egypt led by Muhammad ‘Abduh (1849–1905) are particularly worthy of mention.

More recently, jihad has come to be associated with the program of certain groups (called *jihadis*) who hold that armed force is a necessary means for Muslims to resist the encroachment of a “Zionist-Crusader alliance” by which a variety of false or idolatrous practices are being foisted upon humanity. These practices, which include democratic politics, free market capitalism, and the equality of men and women, are held to violate divine law. Various declarations issued by the leaders of Al-Qaeda and like-minded groups suggest that the spread of these practices constitutes a kind of emergency condition for Muslims, and that in such a condition, fighting becomes an obligation for every Muslim. In contrast with the historic “judgments pertaining to armed struggle,” this contemporary jihad involves fighting without authorization by established heads of state. According to many *jihadis*, the new jihad may also be conducted without regard to distinctions between civilian and military targets. Such points are controversial, with the large majority of Muslims condemning such tactics as violations of Islamic tradition, even while expressing sympathy for some of the causes *jihadis* cite as motivation, viz., the rights of Palestinians, resistance to “undue influence” by the United States and others in the internal affairs of historically Muslim countries, and the desire for effective and legitimate government in Muslim lands.

JIM CROW

Jim Crow was the colloquial term for forms of systematic discrimination employed by whites against African Americans from the second half of the nineteenth century through the first half of the twentieth. The expression insinuates the legal components of the color line (e.g., Jim Crow laws), but also encompasses the cultural and symbolic conventions of hierarchical race relations.

OVERVIEW

The roots of Jim Crow lay deep in the American landscape of slavery. Despite its jocular allusion to a persona, Jim Crow articulated ideologies of black inferiority, which, wrapped in racist rhetoric, signified white supremacy, the control of virtually every aspect of black public life, and access to black private life. As shorthand for the malice of race relations in America, Jim Crow lived out a "strange career," the historian C. Vann Woodward (1908–1999) wrote. "Jim Crow ... did not assign the subordinate group to a fixed status in society. [It was] constantly pushing the Negro further down" (Woodward [1955] 2002, p. 108).

The scholar W. E. B. Du Bois (1868–1963) used the term "the veil" in reference to the barrier separating blacks and whites. Penetrable but immovable, the veil provided African Americans with a view outward, while limiting the ability of whites to see into black society. "Within and without the somber veil of color," Du Bois wrote of black life in The Souls of Black Folk (1903), "vast social forces have been at work,—efforts for human betterment, movements toward disintegration and despair, tragedies and comedies in social and economic life, and a swaying and lifting and sinking of human hearts which have made this land a land of mingled sorrow and joy, of change and excitement and unrest" (pp. 181–182). Behind the veil, then, African Americans engaged in the discourse and action of daily life, often unconcerned with white life. Here, they forged lively communities, built strong institutions, and nurtured generations of activists who took part in the long civil rights movement to "destroy Jim Crow."

As a period of history, the "Jim Crow era" can be set off by two significant decisions made by the U.S. Supreme Court, each determining the constitutionality of racial segregation. On one end, Homer Plessy v. John H. Ferguson 163 U.S. 537 (1896) sanctioned racial segregation and discrimination with the doctrine of “separate but equal,” arguing that the Fourteenth Amendment “could not have been intended to abolish distinctions based upon color, or to enforce social, as distinguished from political equality, or a commingling of the two races upon terms unsatisfactory to either.” On the other end of a timeline, Oliver Brown, et al. v. Board of Education of Topeka, et al. 387 U.S. 483 (1954) outlawed racial segregation in public schools arguing that “separate educational facilities are inherently unequal.” Brown opened the door to question and to challenge other forms of racial inequity.

THE HISTORY OF JIM CROW

Jim Crow far exceeds the temporal markers of Supreme Court decisions, reaching back to the mid-nineteenth century and beyond the modern civil rights movement. Moreover, although Jim Crow is associated mostly with the intractable South, similar patterns, indeed its cultural origins, can be found in the North. The term was being used by the mid-nineteenth century by African Americans and abolitionists to describe the unfair practice of directing black passengers to separate substandard railroad cars. Jimcrow or jimcrowring referred to the injustice of segregating blacks to lesser facilities.

The term Jim Crow originated in American popular culture, specifically in a stage performance, a mocking imitation of a black plantation slave by Thomas Dartmouth “Daddy” Rice (1808–1860), a white entertainer. In the tradition of minstrelsy, Rice blackened his face with burned cork or black wax, wore ragged clothes as a costume, shuffled as he danced, and sang:
Come listen all you galls and boys I's jist from Tuckhoye, I'm going to sing a little song, my name's Jim Crow, Weel about and turn about and do jis so, Ebry time I weel about I jump Jim Crow.

A popular little ditty, “Jump Jim Crow” was a centerpiece of an emerging American popular culture. Popularized, the character Jim Crow and his stage counterpart Zip Coon—an urban dandy from the North—caricatured African Americans as foolish, dim, lazy, sneaky, incompetent, untrustworthy, dishonorable, and without the strength of character required to be an American citizen and white. These degrading stereotypes, infused by distortion and propaganda, provided a substantial base on which to create a rationale for slavery: that African Americans required close supervision, and that only under the control of whites could such people be restrained.

Jim Crow entered a new phase after the Civil War (1861–1865) with enactment of the Black Codes. At the end of the war, in the political chaos that followed Abraham Lincoln’s death in 1865, Confederates claimed southern legislatures and passed laws that restricted the freedom of freedpeople. Replicating slavery in all ways except name, the Black Codes required blacks to accept unfavorable work contracts, limited their mobility, and denied them citizenship rights. As traditional powers collapsed at the beginning of Reconstruction, African Americans claimed and exercised the citizenship rights guaranteed by the Thirteenth, Fourteenth, and Fifteenth amendments. Southern whites viewed this new societal arrangement as a corruption of race and gender relations that historically favored white males.

At the end of Reconstruction, when power returned to white southerners, distorted descriptions of Reconstruction governments signified whites’ resentment for their losses and provided the tinder for racial fires to burn through the turn of the century. Referring to black political participation as “Negro rule” or “Negro domination,” and distorting the work of Reconstruction legislatures as corrupt and immoral, white politicians determined that black power would neither continue nor return. By the end of the nineteenth century, every southern state and community had forged a set of constitutional amendments, legislation, or legal maneuvers to disfranchise African American men by force of law and intimidation. Almost every school was racially segregated and disparate in condition. Consistently, blacks were employed in the most difficult jobs for the lowest of wages.

As the color line itself solidified at the turn of the nineteenth century, Jim Crow imposed on black people clear tactical disadvantages: restricted economic possibilities, narrow educational opportunities, inadequate housing options, high rates of death and disablement, persistent unemployment, and unrelenting poverty. Inasmuch as Jim Crow represented the race problem described by Gunnar Myrdal (1898–1987) in his 1944 treatise The American Dilemma, it was Jim Crow that created the race quandary; whites constructed the obstacles African Americans confronted, while also blaming them for their conditions, denying them access to the resources of problem solving, and daring them—under threat of violence—to complain, protest, or advance.

Jim Crow laws segregated not only public venues but also restaurants, restrooms, hospitals, churches, libraries, schoolbooks, waiting rooms, housing, prisons, cemeteries, and asylums. Customary signs noting “colored” and “white” or “white only” marked off the southern landscape, dividing public conveyances, public accommodations, and birth, residence, and death. Purportedly equal, these circumstances usually were unequal. Laws regulated not only segregation but also social relations. In most states, blacks and whites could not marry by law, or socialize by custom. According to a Maryland law, “all marriages between a white person and a negro, or between a white person and a person of negro descent, to the third generation, inclusive … are forever prohibited, and shall be void.” Blacks and whites could not compete against each other, whether at checkers or college sports. A Mississippi law read, “any person guilty of printing, publishing or circulating matter urging or presenting arguments in favor of social equality or of intermarriage between whites and negroes, shall be guilty of a misdemeanor.”

ENFORCEMENT

Jim Crow could be fluid, amorphous, and nuanced. Because the laws and practices of Jim Crow varied from place to place, the scheme was confusing, and African Americans were careful to learn the racial etiquette of the locales to which they traveled. In addition, different groups of African Americans, rural and urban, women and men, and people of varying classes, experienced Jim Crow in different ways. Inasmuch as women and men faced differential limitations of Jim Crow, civil rights and women’s movement activist Pauli Murray (1910–1985) coined the term Jane Crow to describe sex discrimination against women, and race and sex discrimination against black women. African Americans could not always unify against Jim Crow because segregation could benefit some to the detriment of others. Black colleges thrived, for example, but most segregated public elementary and secondary schools struggled with inadequate resources to prepare students for higher education.

Finally, protests or challenges to Jim Crow often proved futile, given law enforcement’s complicity in the
structure. From emancipation to the turn of the century, the Ku Klux Klan operated as a paramilitary arm of the Democratic Party in the South. The Klan, nightriders, red shirts, and other white terrorists intimidated African Americans with personal attacks, school burnings, and lynchings. African Americans rarely served as policemen, sheriffs, or deputies before the late 1940s. During the 1950s and 1960s, the connections between municipal and state governments, law enforcement, and racial violence were well known by officials and citizens alike. White officers were known to harass black people, disrupt black neighborhoods, and assault black women. Arrested for inflated charges, denied satisfactory counsel, and serving harsh sentences, African Americans were further disadvantaged in the courtroom. Rarely did they receive good counsel, nor could they serve on juries. When black lawyers could appear in the courtroom to argue cases, white judges and juries rarely listened. All-white juries decided against black defendants, even in the most obvious cases of innocence, but rarely convicted white defendants, despite evidence of guilt. African Americans—including the innocent—suffered the harsher punishments of extended jail time, forced farm labor, and peonage. Even women could be placed on the chain gangs working the roads and tracks across the South.

Extralegally, Jim Crow justice was rough. According to the National Association for the Advancement of Colored People (NAACP), between 1889 and 1918 over 2,500 African Americans were lynched: captured and viciously murdered by mobs. Ostensibly, accusations of rape provided the reason for lynching, yet rarely were these cases validated. A form of social control and vengeance, lynching followed when a black person stepped out of line, did not demonstrate enough deference, acted out of antagonism, committed assault or manslaughter as self-defense, or spoke out of turn. Through the first half of the twentieth century, furthermore, riots flared as an expression of white antagonism, among them the Wilmington Riot of 1898, the Atlanta Riot of 1906, the East Saint Louis Riot of 1917, and the Tulsa Riot of 1921. In each of these and other conflagrations, whites expressed their racial rage by entering black neighborhoods to assault men, women, and children, and by burning down homes, schools, and churches. African American veterans in uniform also were targets of random attack, subject to vengeance for wearing a symbol of American citizenship.

AFRICAN AMERICANS AND JIM CROW

For these reasons, Jim Crow presented a formidable opponent—one that could divide its victims against themselves. Numerous leaders stepped forward to speak to the quandary of race relations. Booker T. Washington (1856–1915) advised black men to shift their focus from electoral politics to economics, to take up the trades, farming, and domestic and service work in order to build character and capital. While Washington supported industrial education, Du Bois recommended that the most talented of black folk be trained in the liberal arts so that they could emerge as leaders of the race. Ida B. Wells-Barnett (1862–1931), a fearless antilynching campaigner, took up the mantle of agitation, advising African Americans to protect themselves and to leave the South altogether.

The question of migration as a form of protest dominated black discourse and action after emancipation, and as the century turned, a trickle of black southerners, mostly women, began to leave the land for the cities of the South and the North. They laid the groundwork for what was later called the Great Migration, when millions of African Americans left the brutalities of the South for the possibilities of the North. Black migrations were fueled by several factors. African Americans hoped to escape the tyranny of the South, especially economic oppression. The importunate character of sharecropping pressed families to give up the land for the city. There, however, they found new sets of barriers to employment or improved living conditions. Nevertheless, as the war economies expanded and European immigration slowed, African Americans found employment in the industries and the trades. Black people also migrated to find personal freedom not available to them in the South. African American women, for example, migrated to escape the persistent danger of public sexual assault by white and private assault by black men. As migrants within the South, women also laid the foundations upon which black southern communities were built, and it is here that the war against Jim Crow took place.

In urban areas, African Americans upbuilt communities from small settlements of freedpeople into dynamic neighborhoods of homes, institutions, and organizations. Although segregated, schools instilled a sense of race pride and responsibility in children. Churches served multiple roles, as community, political, and recreational spaces. Teachers, professors, undertakers, doctors, lawyers, and nurses served to uplift the black community. Held in high esteem, they presented not only models to emulate, but also a daily reminder of black accomplishment despite Jim Crow. National organizations like the NAACP, the National Negro Business League (NNBL), and black fraternities and sororities all functioned to improve the quality of life for African Americans. Founding segregated YWCAs, YMCAs, Boy’s Clubs, Boy Scouts, and Girl Scouts, adult African Americans supervised the development of young people with an eye toward the demands of citizenship. Indeed, although historians have called the
early years of Jim Crow “the Nadir,” the lowest point in African American history, the period also was the zenith of the black press, black business, black church organizations, and the black women’s club movement as African Americans set about the work of race progress.

Still, the disadvantages of Jim Crow far outweighed the advantages, and beginning in the 1930s, African Americans took up a number of civil rights crusades. The NAACP, for example, began the battle against educational inequality, with the support of local branches. Local communities also engaged in “don’t-buy-where-you-can’t-work” campaigns, denying their dollars to businesses that did not employ black people. Veterans returned from a war against racism expecting to be accorded citizenship rights commensurate with their sacrifices. Turned back at the courthouses, they launched voting rights campaigns. By the 1940s, several events signaled that the demise of Jim Crow had begun. In Texas, the Supreme Court decision in Smith v. Allwright, Election Judge, et al. 312 U. S. 649 (1944) ended the all-white primary, opening the southern electoral process to black voters. In 1948 President Harry Truman (1913–2003) signed Executive Order 9981, desegregating the armed forces. Finally, the Supreme Court decision in Brown v. Board of Education sounded the end of constitutionally sanctioned Jim Crow in public schools, making way for African Americans to demand the integration of all public facilities and accommodations.

Just as Jim Crow was not a strictly definable historical period, the struggle against it was protracted. Using forms of direct action, nonviolent protests, and demonstrations, civil rights activists of the 1950s and 1960s were determined to break the back of Jim Crow, and they were successful, at least as far as the legal arena was concerned. Inasmuch as Jim Crow was a milieu that permeated culture and ideology historically, the struggle against American apartheid continues.

JINGOISM

The term jingoism dates from the late 1870s. The jingoes, so termed after a music-hall song, were vociferous supporters of a strong British foreign policy in the Near East. Jingoism subsequently came to define any foreign policy in support of national interests that took its cue from public opinion. For social scientists, jingoism stands as one of the manifestations of nationalism in the Western world in the half-century leading up to World War I (1914–1918).

In the spring of 1877, Russia went to war with Turkey. The Conservative British government, led by Benjamin Disraeli (1804–1881), was concerned that Constantinople might fall to the Russians and that this would endanger the security of British routes to its Indian empire. Neutrality was declared, but conditional on the safeguarding of British interests. Toward the end of the year, it seemed as if these interests might be threatened, and the possibility loomed that Britain would become involved in a reprise of the Crimean War of the 1850s. A strong peace campaign urged the government not to get involved in the war, and for some weeks it seemed to carry all before it. But then, in January 1878, the peace meetings began to be broken up by supporters of a strong policy. The changing mood of the public was evident also in popular entertainment. G. W. Hunt (c. 1830–1904) wrote and composed a song to reflect and express the views of those who wanted the government to stand firm in the face of the Russian advance. It played on a deep-rooted Russophobia in Britain, one verse going:

The ‘Dogs of War’ are loose, and the rugged Russian Bear,
Full bent on blood and robbery, has crawled out of his lair,
It seems a thrashing now and then will never help to tame
Jingoism

That brute, and so he’s bent upon the ‘same old game.’

Sung by G. H. Macdermott (c. 1845–1901) in London, and then on a provincial tour, the song became a popular hit, its rousing chorus giving the jingoes their name:

We don’t want to fight,  
But by Jingo if we do  
We’ve got the ships, we’ve got the men, we’ve got the money too.  
We won’t let the Russians get to Constantinople.

Thoroughly alarmed at the changing mood of the public, and at the violent breakup of their meetings, the advocates of peace described their opponents as jingo, “the new tribe of music-hall patriots who sing the jingo song.”

From that moment on, through the late nineteenth and early twentieth centuries, jingoism was a term used by opponents of an assertive foreign policy. Moderate Conservatives as well as Liberals and socialists were alarmed at what they saw as the undue influence on policymaking of raucous public opinion. It was not that there had not previously been virulent antiforeign sentiment, against the Spanish in the early modern period, and against the French in the eighteenth and early nineteenth centuries. A fear of Russia itself had deep roots. What was new, and what distinguished jingoism from these earlier manifestations, was that it coincided in time with Britain becoming increasingly democratic. Most urban working-class men had become entitled to vote in 1867, and this was extended to those living in rural areas in 1884. The worry of the elite classes, whatever their politics, was that an undereducated electorate, swayed by a cheap popular press and music-hall songs, would exercise an undue influence on the conduct of foreign policy.

Lord Derby (1826–1893), who had been Disraeli’s foreign secretary in 1878 but lost his job when Disraeli gave way to the jingoes, complained in 1882 that the leading idea of jingoism seemed to be “that no State can be in a healthy condition that is not occasionally pitching into its neighbour.” Lord Salisbury (1830–1903), Conservative prime minister for much of the late nineteenth century, argued in 1897 that an arbitration system “would be an invaluable bulwark to defend the Minister from the jingoes.” The most extended attack on jingoism came from the Liberal publicist J. A. Hobson (1858–1940), whose The Psychology of Jingoism (1901) was prompted by the renewed breakup of peace meetings during the South African War of 1899 to 1902. Hobson explained jingoism by linking together the fashionable psychology that was alarmed by the “herd instinct” of the populations of the large cities of the modern world and the growth of the popular press, which seemed to pander to the worst instincts of these urban masses.

Detailed research on those who might be called active jingoes—those who tried to break up peace meetings—suggests that they were often associated with other right-wing populist causes such as fair trade (to keep out foreign imports) and opposition to immigration. Medical students, hardly typical of an undereducated urban mass, featured prominently in the rowdy meetings. Many jingoes had links with the Conservative Party. Although the party leaders were often distinctly lukewarm about jingoism, there is much evidence that, as in the 1900 general election where the South African war was the dominant issue, Conservatives gained by their association with an assertive foreign policy. More generally, a nationalistic foreign policy appealed to the growing lower middle class of clerks and shopkeepers who may have been trying to overcome their anxiety about their status by affirming loyalty to the nation.

Jingoism as a word crossed the Atlantic, its use particularly prevalent in the 1890s. In 1896 the Nation in New York referred to “Jingoish ideas of America’s past and future,” and in 1898 President William McKinley (1843–1901) was reported to have said that he “will not be jingoed into war.” But whether or not the word jingo was used, all Western countries were familiar with the phenomenon prior to World War I. In France, chauvinism was the equivalent of jingoism.

The experience of World War I put an end to the more overt assertions of national aggression. There were people who continued to hold views similar to the jingoes, but they were more on the fringe. The right-wing nationalism of the 1920s and 1930s came in the even more alarming form of fascism. After World War II (1939–1945), critics of British foreign policy or public opinion sometimes blamed jingoism, for example, for the war over the Falkland Islands in the 1980s. But as a permanent presence on the political scene, jingoism had a lifespan of some forty years preceding World War I.

JINNAH, MOHAMMED ALI
1876–1948

Mohammed Ali Jinnah was born in 1876 in Karachi, then a small port town on the western coast of British India. A bright and ambitious young boy, he soon found his way to London and joined Lincoln's Inn, one of the best-known legal institutions in England. Jinnah acquired many things from British culture, perhaps most important of all, a sense of respect for the law.

On returning to India, Jinnah set up practice in Bombay and soon made a mark on society as a prominent leader. He became a passionate nationalist for the freedom of India and for unity between the two major communities of South Asia—Hindus and Muslims. He was called the “ambassador of Hindu-Muslim unity” by Gopal Krishna Gokhale (1866–1915), the distinguished Hindu leader. In 1918 Jinnah fell in love with and married Ruttie, who was half his age, and they had one child, a daughter called Dina.

In the 1920s the politics of India was changing dramatically. Mohandas Gandhi (1869–1948) and Jawaharlal Nehru (1889–1964) emerged as superstars to lead the Indian National Congress. The main Muslim party, the Muslim League, could not field anyone of their stature. Uncomfortable with what he saw as the emergence of communal politics, Jinnah was finding it difficult to place himself.

When Ruttie died in 1929, Jinnah left India to practice law in London. In the meantime, the Muslims of India became alarmed at the growth of what they saw as Hindu communalism in politics and the vulnerability of Muslims. Several delegations visited Jinnah and asked him to return to India and lead the Muslims.

Jinnah was persuaded to return and by the late 1930s galvanized the Muslims into a political force. He changed the way he dressed and even his arguments to reflect a more Islamic identity. In a historic Muslim League session in 1940 in Lahore, Jinnah introduced the idea of Pakistan, a defined political entity for the Muslims of India. Jinnah then led a full-scale campaign to create Pakistan in the face of vigorous opposition from the Indian National Congress and, initially, from the British.

In August 1947 Pakistan was carved out of the Muslim dominated areas of the northwest of India and the province of Bengal in the east. Although Jinnah had warned against it, Lord Louis Mountbatten (1900–1979), the viceroy, ensured that the two major provinces of India, the Punjab and Bengal, were cut in half. This division plunged the subcontinent into a bloodbath as some fifteen million people escaped communal rioting to migrate to the new homelands—Hindus and Sikhs escaping from Pakistan to India, and Muslims from India going to Pakistan. It is estimated that about two million people died in the communal frenzy that summer.

Jinnah became the first governor-general of the independent state of Pakistan, which was then the largest Muslim nation on earth. But the moment of triumph was darkened for Jinnah by the scale of the death and destruction. Depicted as a cold and formal man, Jinnah could not control his emotions at the scale of the tragedies unfolding around him. In speech after speech, he talked of the “harrowing accounts of the terrible happenings” and his “deep distress and heavy heart.” Fatima Jinnah, his sister and constant companion, wrote of Jinnah’s emotional condition in the last months of his life. “As he discussed with me these mass killings at the breakfast table, his eyes were often moist with tears. The sufferings of Muslim refugees that treked from India into Pakistan, which to them had been the Promised Land, depressed him” (Jinnah 1987, p. 11).

In the midst of the chaos, Jinnah set up an entirely new government based in Karachi. His first two speeches to the Constituent Assembly in August that year clearly outlined his vision of a modern Muslim state: while inspired by the principles of Islam, the rights of everyone were to be respected. Jinnah specifically mentioned the freedom that non-Muslims would enjoy in Pakistan. He condemned nepotism and corruption in the strongest terms.

Already ill, Jinnah was now physically and emotionally exhausted. He spent several months in Ziarat, a hill station in Baluchistan, in the hope of recovering his health. In September 1948 Jinnah died in Karachi.

Pakistanis saw Jinnah as a leader who gave them their own homeland against impossible odds, and they called him the Quaid-e-Azam, or the great leader. Alan Campbell Johnson (1913–1998), a key official of Lord Mountbatten, described Jinnah thus: “Here indeed is Pakistan’s King Emperor, Archbishop of Canterbury, Speaker and Prime Minister concentrated into one formidable Quaid-e-Azam” (Mitchell 1997). Jinnah’s grand
mausoleum in Karachi is a main attraction for foreigners and Pakistanis alike.

With the triumph of Jinnah’s life, there were also great tragedies that still haunt South Asia. One of these is the unresolved dispute over the large and important state of Kashmir. Pakistan has advocated that a plebiscite be held so that Kashmiris can decide their own fate. Its mainly Muslim population and contiguous territory to Pakistan have led Pakistanis to believe that Kashmir should have become part of Pakistan in 1947. However, its Hindu ruler opted for India. Pakistanis suspected that the friendship between the Mountbattens and Nehru, the first prime minister of India, was responsible for this injustice. Three wars have been fought between India and Pakistan over Kashmir, and now that both countries are nuclear powers, the region has been described by President Bill Clinton as the most dangerous place in the world.

Jinnah’s life shows the importance of personal relationships in politics. While Jinnah was comfortable dealing with such contemporaries as Gandhi and Motilal Nehru (1861–1931), father of Jawaharlal, there was little rapport between him and the Mountbattens or their friend Jawaharlal Nehru. They, in turn, saw him as a figure from the past and spoke unkindly of him. Jinnah’s relationship with B. R. Ambedkar (1891–1956), the leader of the Dalit—or those once called the “untouchable” caste—is surprisingly neglected. Jinnah and Ambedkar came to represent the two important minority groups of India—the Muslims and the Dalit. Both were suspicious of Gandhi’s identification with mainstream Hinduism and warned against Ram Raj, or the rule of upper-caste Hindus who used Lord Ram as a symbol of Hindu revivalism. Ambedkar was supportive of the idea of Pakistan, but he did point out the problems its creation would pose for Hindus and Muslims in general. While Jinnah appreciated Ambedkar’s criticism of Hinduism, he was also aware of Ambedkar’s vitriolic criticism of some of the social practices of Indian Muslims. The tactical alliance between the Muslims and the Dalit that could have altered the shape of Indian politics thus never took place.

Considering the scale of his achievement, it is not surprising that Jinnah remains a subject of discussion and debate. Historians continue to interpret his position on the creation of Pakistan. For some, the Pakistan movement was the logical outcome of the politics and social ideas of the first half of the twentieth century (Ahmed 1997; Wolpert 1984, 2006). Others have argued that Jinnah was using the demand for Pakistan as a bargaining chip to improve the position of the Muslim minority in India (Jalal 1985). Jinnah would have thus resolved the contradiction between a demand for a separate Muslim state and the need for a strategy that would safeguard the interests of all Indian Muslims. No one, however, can deny that Jinnah did what few have done in history: almost single-handedly, he created a nation.

JOB GUARANTEE

A job-guarantee program is one in which government promises to make a job available to any qualifying individual who is ready and willing to work. Qualifications required of participants could specify age range (e.g., teens), gender, family status (e.g., heads of households), family income (e.g., below poverty line), educational attainment (e.g., high school dropouts), residency (e.g., rural), and so on. The most general program—sometimes called an employer of last resort (ELR) program—would provide a universal job guarantee by which governments promises to provide a job to anyone legally entitled to work.

Many job-guarantee supporters see employment not only as an economic condition, but also as a right. L. Randall Wray and Mathew Forstater (2004) justify the right to work as a fundamental prerequisite for social justice in any society in which income from work is an important determinant of access to resources. Philip Harvey (1989) and John Burgess and William F. Mitchell (1998) argue for the right to work on the basis that it is a fundamental human (or natural) right. Such treatments find support in modern legal proclamations such as the United Nations Universal Declaration of Human Rights,
the U.S. Employment Act of 1946, and the Full Employment Act of 1978. Amartya Sen (1999) supports the right to work on the basis that the economic and social costs of unemployment are staggering, with far-reaching consequences beyond the single dimension of a loss of income (see also Rawls 1971). William Vickrey identified unemployment with “cruel vandalism,” outlining the social and economic inequities of unemployment and devising strategies for its solution (Forstater and Tcherneva 2004). A key proposition of such arguments is that no capitalist society has ever managed to operate at anything approaching true full employment on a consistent basis. Further, the burden of joblessness is borne unequally, concentrated among groups that already face other disadvantages: racial and ethnic minorities, immigrants, younger and older individuals, women, people with disabilities, and those with lower educational attainment. For these reasons, government should and must play a role in providing jobs to achieve social justice.

There are different versions of the job-guarantee program. Harvey proposed to provide to anyone unable to find work a public sector job with pay approximating a “market wage”: more highly skilled workers would receive higher pay (1989). Argentina’s Jefes program (examined below) targets heads of households only, offering a uniform basic payment for what is essentially half-time work. In another model, initially proposed by Hyman Minsky (1965) and developed further at the Center for Full Employment and Price Stability, University of Missouri—Kansas City, and independently at the Centre of Full Employment and Equity, University of Newcastle, Australia, the federal government provides funding for a job-creation program that offers a uniform hourly wage with a package of benefits (Wray 1998; Burgess and Mitchell 1998). The program could provide for part-time and seasonal work as well as other flexible working conditions as desired by the workers. The package of benefits would be subject to congressional approval, but it could include health care, child care, payment of Social Security taxes, and usual vacation and sick leave. The wage would also be set by Congress and fixed until Congress approved a rate increase, much as the minimum wage is currently legislated. The perceived advantage of the uniform basic wage is that it would limit competition with other employers because they could attract workers out of the ELR program by offering them a wage slightly above the program wage. Since the basic wage is held constant, it will not go up in competition with private employers, to try to bid workers away from them.

Proponents of a universal job-guarantee program operated by the federal government argue that no other means exists to ensure that everyone who wants to work is able to obtain a job. Advantages include poverty reduction, amelioration of many social ills associated with chronic unemployment (such as health problems, spousal abuse and family breakups, drug abuse, crime), and enhanced skills from training on the job. Such a program would improve working conditions in the private sector because employees would have the option of moving into the ELR program; hence, private sector employers would have to offer a wage and benefit package and working conditions at least as good as those offered by the ELR program. The informal sector would shrink as workers become integrated into formal employment, gaining access to protection provided by labor laws. There would be some reduction of racial or gender discrimination because unfairly treated workers would have the ELR option, although, of course, an ELR program by itself cannot end discrimination. Still, it has long been recognized that full employment is an important tool in the fight for equality (Darity 1999). Mathew Forstater has emphasized how an ELR program could be used to increase economic flexibility and to improve the environment, as projects can be directed to mitigate ecological problems (1999).

In addition, some supporters emphasize that an ELR program with a uniform basic wage helps to promote economic and price stability by acting as an automatic stabilizer as employment in the program grows in recession and shrinks in economic expansion, counteracting private sector employment fluctuations. The federal government budget becomes more counter-cyclical because its spending on the ELR program likewise grows in recession and falls in expansion. Furthermore, the uniform basic wage reduces both inflationary pressure in a boom and deflationary pressure in a bust. In a boom, private employers can recruit from the ELR pool of workers, paying a premium over the ELR wage. The ELR pool acts like a “reserve army” of the employed, dampening wage pressures as private employment grows. In recession, workers downsized by private employers can work at the ELR wage, which puts a floor to how low wages and income can go.

Critics argue that a job guarantee would be inflationary, and they point to a version of a Phillips Curve approach, according to which lower unemployment necessarily means higher inflation (Sawyer 2003). Some argue that an ELR program would reduce the incentive to work, raising private sector costs because of increased shirking, because workers would no longer fear job loss; in fact, workers might be emboldened to ask for greater wage increases. Some argue that an ELR program would be so big that it would be impossible to manage; some fear corruption; others argue that it would be impossible to find useful things for ELR workers to do; still others argue that it would be difficult to discipline ELR workers. It has been argued that a national job guarantee would be too expensive, causing the budget deficit to grow to unsus-
tainable levels, and that higher employment would worsen trade deficits (Aspromourgous 2000; King 2001). (See Mitchell and Wray 2005 for responses to all of these critiques.)

There have been many job-creation programs implemented around the world, both narrowly targeted and broad-based. The United States’ New Deal of the 1930s contained several moderately inclusive programs, including the Civilian Conservation Corps and the Works Progress Administration. Sweden developed broad-based employment programs that virtually guaranteed access to jobs, until government began to retrench in the 1970s (Ginsburg 1983). In the aftermath of its economic crisis that came with the collapse of its currency board in December 2001, Argentina created Plan Jefes y Jefas in April 2002, which guaranteed jobs for poor heads of households (Tcherneva and Wray 2005). The program successfully created two million new jobs that provided not only employment and income for poor families, but also needed services and free goods to poor neighborhoods. More recently, India passed the National Rural Employment Guarantee Act (2005), which commits the government to providing employment in a public-works project to any adult living in a rural area. The job must be provided within fifteen days of the applicant’s registration, and must provide employment for a minimum of 100 days per year (Hirway 2006). These real-world experiments provide fertile ground for testing the claims on both sides of the job-guarantee debate.

JOHANSON, DONALD

1943–

Donald Carl Johanson was born in Chicago, Illinois, on June 28, 1943. He earned a BA from the University of Illinois, Urbana-Champaign, in 1966 and an MA and a PhD from the University of Chicago’s Anthropology Department in 1970 and 1974, respectively. Johanson wrote his doctoral thesis on variability in the dentitions of bonobos and chimpanzee subspecies, chiefly under the guidance of Albert A. Dahlberg, the founder of U.S. dental anthropology. Before getting his doctorate, Johanson worked variously on archaeological projects in Iowa and Illinois, as a research assistant in a dental anthropological study on Kodiak Island, Alaska, and as a research assistant to F. Clark Howell with the Omo Research Expedition to the Lower Omo Basin, Ethiopia (1970–1971).

In 1972 Johanson joined the International Afar Research Expedition to Ethiopia’s Afar Depression, where the following year he found four Plioene hominid fossils, consisting of femoral fragments and a knee joint (A.L. 129-1), that clearly indicated bipedal posture. Initially, Johanson thought that more than one species was represented, but when the sample was greatly augmented by
the discovery in 1974 of a notable portion of a skeleton (AL-288-1, dubbed “Lucy”), and a large collection of remains of hominids at locality 333 (dubbed “the first family”) in 1975–1977, he came to believe that the findings represented a variable single species, *Australopithecus afarensis*, which lived between 3 and nearly 4 million years ago. Furthermore, he concluded that contemporaneous specimens from 3.5-million-year-old deposits at Laetoli, Tanzania, discovered by a team led by Mary Leakey, were also *Australopithecus afarensis*. Johanson’s use of one of the Laetoli mandibles (LH-4) as the type specimen for *Australopithecus afarensis* and his negative comments about Richard, Mary, and Louis Leakey and other professional colleagues in *Lucy: The Beginnings of Humankind* (1981) and *Lucy’s Child: The Discovery of a Human Ancestor* (1989) and on the lecture circuit detracted from his overall scientific credibility among some peers. Nonetheless, Johanson stands as the foremost U.S. contributor to the hominid fossil record during the 1970s, the 1980s, and the early 1990s.

Beginning in 1972 Johanson served as a curator of anthropology, then of physical anthropology, at the Cleveland Museum of Natural History and was on the faculties of Case Western University in Cleveland, Ohio, and Kent State University in Kent, Ohio. In 1981 he founded the Institute of Human Origins (IHO) in Berkeley, California. In 1998 the IHO relocated to the University of Arizona, where Johanson continues as director and occupies the Virginia M. Ullman Chair in Human Origins. He and his colleagues at IHO have continued to augment knowledge and understanding of human development via empirical paleoanthropological data from the field, educational television films—most notably, *Lucy in Disguise* (1980), *The First Family* (1980), and *In Search of Human Origins* (1994)—public lectures, presentations at scientific meetings, and publications. Johanson has also trained many doctoral and postdoctoral students, some of whom are from Ethiopia and other nations where hominid fossils are found.

**JOHN HENRYISM**

John Henryism (JH), a psychological construct formally proposed in 1983 by Sherman James and colleagues (James et al. 1983), is defined as a “strong behavioral predisposition to cope actively with psychosocial environmental stressors” (James 1994, p. 163). JH is characterized by three factors: (1) efficacious mental and physical vigor; (2) a strong commitment to hard work; and (3) a single-minded determination to succeed. James and colleagues hypothesized that for persons lacking sufficient socioeconomic resources, active coping (i.e., sustained cognitive and emotional engagement—in other words, prolonged determination to succeed) with persistent psychosocial and environmental stressors may increase the risk of negative health outcomes.

JH takes its name and is inspired in part by the story of John Henry, the fabled “steel-driving man.” According to legend, John Henry was an uneducated black steel driver who participated in a competition with a mechanical steam-powered drill. Though he rallied the physical strength needed to win the competition, he died soon after from overwhelming mental and physical fatigue. For James, the story of John Henry was a metaphor for the empirical literature that links active coping with psychosocial stress to dysregulation of the sympathetic nervous system (which may heighten blood pressure and hypertension risk).

James and his colleagues conducted a number of cross-sectional investigations of the JH hypothesis in then-rural North Carolina. The initial 1983 study of 132 working-class black men aged seventeen to sixty years demonstrated that black men with low education and high JH had higher mean diastolic blood pressure than other subgroups, though the difference was not statistically significant. However, in their 1984 follow-up study, James and his colleagues found a significant interaction between JH and perceived job success in the prediction of diastolic blood pressure among 112 black male workers. In 1987, James et al. recruited a sample of 820 black and white men and women aged twenty-one to fifty years, and found that blacks with high JH and low socioeconomic status (SES) were almost three times as likely to be hypertensive, compared to blacks of high socioeconomic position; no similar relationship was found among whites.
James's group focused their 1992 study on a much larger sample of African Americans from an eastern North Carolina county that was more urbanized and socioeconomically diverse than the areas in their previous studies. When the traditional JH hypothesis—high JH and low SES constitutes risk—was not supported, James posited that high JH should only be deleterious for those of lower SES who also have high levels of perceived stress. Indeed, post hoc analyses revealed significantly elevated blood pressure levels among those with high JH and low SES, but only for those who also reported high levels of perceived stress.

In addition to James’s early work, a number of other studies have investigated the JH hypothesis in sociodemographically diverse samples, with a wide array of health outcomes. Results from these studies have been mixed. For example, Lynda Wright and colleagues (1996) demonstrated that high JH scores were associated with higher resting blood pressure, higher total peripheral resistance, and lower cardiac index among 173 healthy white and black children aged ten to seventeen. William Wiist and John Flack (1992) found that high JH, low SES participants were significantly more likely to have higher cholesterol levels (> 240 mg/dl). In a sample of 600 African American men and women, William Dressler and colleagues (1998) found an interaction between gender and John Henryism such that for men, higher JH was associated with increased systolic blood pressure and hypertension risk, whereas elevated JH was associated with lower blood pressure and hypertension risk among women.

Despite these and other positive findings, a number of studies have failed to support the traditional JH hypothesis. To illustrate, Linda Jackson and Lucile Adams-Campbell (1994), found no JH effect on blood pressure among urban black college students. A study of 658 Nigerian civil servants yielded a nonsignificant trend for higher blood pressure among those with high levels of both JH and socioeconomic status (Markovic et al. 1998). Anita Fernander and colleagues (2005) found that participants with low education who had low JH reported higher nicotine dependence scores, compared to any other subgroup. Finally, Vence Bonham and colleagues (2004) found that better self-reported physical health among a sample of high socioeconomic-position African American men was marginally associated with high John Henryism.

Methodological inconsistencies as well as differences in the sociodemographic composition of study samples may partly explain these mixed findings. For example, although JH originally was thought to constitute risk in the context of lower socioeconomic position, a number of studies have studied JH as an independent risk factor (i.e., without modeling the JH x SES interaction). Most studies investigating JH independently have shown no association with the studied health outcomes. Certainly, there is controversy regarding the most appropriate measures of SES, though there is consensus that the definition varies by population. A wide variety of socioeconomic indicators have been studied in association with JH, but no clear pattern has emerged. A largely unresolved issue concerns whether JH is most predictive in specifically socially disadvantaged populations, or whether it is more widely occurring.

Those researching the JH construct have examined a range of health outcomes, but have been primarily focused on cardiovascular parameters (particularly blood pressure). Other outcomes with positive findings include cholesterol, cigarette smoking, pain susceptibility, and stress-related illness. JH research has been conducted with various samples (e.g., older populations, high school and college students, clinical samples) of various racial-ethnic, socioeconomic, and geographic composition. Though support for the JH hypothesis was originally found among populations in the American southeast, the construct has been widely investigated in a range of populations throughout the United States and in European and African countries, and in both urban and rural settings. A growing area of JH research concerns the role of JH in predicting the adoption of adverse health behaviors (including smoking, alcohol dependence, and stress-related eating). A new body of work uses JH in the clinical realm to learn more about the health effects of high-effort coping among those with chronic illness. A recent study has estimated the proportion of JH behaviors that are inherited (Whitfield et al. 2006). The JH literature proposes a novel and compelling hypothesis for understanding the promotion of disparities in a number of key health outcomes. The body of evidence investigating JH is replete with areas for additional inquiry, thus ensuring that JH research will continue.

JOHNSON, LYNDON B.

1908–1973

As thirty-sixth president of the United States, Lyndon Baines Johnson presided over one of the most turbulent periods in American history. His administration's confrontations with both severe domestic turmoil and international conflict highlight the potential and constraints of the modern presidency.

Johnson was born in Stonewall, a poor rural outpost located on the Pedernales River in central Texas. His political education began at an early age, as his paternal grandfather regaled his progeny with stories of his participation in the Populist movement of the late nineteenth century, while Johnson's father was active in state and local politics and served in the Texas state legislature during Johnson's youth.

Still, while politics played an important role in Johnson's life in childhood, it was during his attendance at Southwest Texas State Teachers College in San Marcos that Johnson developed the attitudes and qualities that would suffuse his political career. Upon his arrival at the college, he quickly set about the task of studying the school's internal dynamics and used the information he garnered to place himself close to its centers of power, a pattern he repeated several times during his participation in national politics. It was also at this juncture that Johnson articulated—in a series of editorials in the college newspaper—much of the philosophy that guided his political activities and approach to government later on.

After graduation, Johnson took a high school teaching position in Houston. Shortly thereafter, however, Johnson began to dabble with increasing seriousness in national politics, first as campaign manager for a Texas state legislator and then as a staffer for a newly elected member of the U.S. Congress. This latter position finally brought Johnson to Washington, D.C., where he remained for much of the duration of his political career. And as he had done in San Marcos, Johnson devoted his time to unearthing the sources of influence in the federal legislature and, armed with that knowledge, maneuvering himself as close to its power center as possible.

Johnson entered elective politics in 1937, when he was sent to Congress in a special election in Texas's Tenth District. He served in the House of Representatives until his 1948 election to the Senate, where he rose quickly through the Democratic Party ranks to become Senate minority leader in 1953 and majority leader in 1955. It was in these roles that Johnson's political career reached its zenith. Perhaps most notably, it was in these leadership roles that he perfected what quickly came to be known as "the Johnson treatment": a repertoire of psychological appeals and talking points that Johnson employed to enforce party discipline and more generally coax and strong-arm recalcitrant colleagues to rally around his legislative agenda.

The Senate leadership roles thus presented an ideal platform for Johnson to exploit the deep understanding of legislative power he had cultivated during his congressional career. As a Texan who brought to politics both pragmatism and a keen awareness of the possibilities for using the power of government to address social problems, Johnson was pivotally poised to mediate between the congressional Democratic Party's liberal and southern factions. In many ways, therefore, being Senate majority leader offered Johnson the opportunity to exert substantial influence over the course of national politics and public policy.

Nevertheless, Johnson left the Senate in 1961 to serve as President John F. Kennedy's vice president until
November 22, 1963, when Kennedy was assassinated during a political tour in Dallas, Texas. Johnson was sworn in as president that same afternoon and served out the remaining year of Kennedy's term. Then in November 1964 he was elected president in his own right in a landslide victory against the Republican Party's ultraconservative candidate, Barry Goldwater.

The hallmark of Johnson's presidency was the Great Society program, which, as he described it in his commencement address at the University of Michigan in 1964, sought to "enrich and elevate our national life, and to advance the quality of our American civilization" (Johnson 1965, p. 704). Specific initiatives included the declaration of a War on Poverty; the introduction of various laws aimed at improving education, Social Security, health care, and the environment; and the creation of Head Start, the Job Corps, and the National Endowment for the Arts and the Humanities. Civil rights also figured prominently in Johnson's domestic agenda. One of his first acts as president was to fulfill the Kennedy administration's promise to support an antisegregation bill by working tirelessly to secure passage of the omnibus Civil Rights Act of 1964. A dramatic wave of protests in Alabama the following winter led him to champion ratification of the Voting Rights Act of 1965. And although Congress failed to enact the civil rights legislation he introduced in 1966 and 1967, Martin Luther King Jr.'s assassination created favorable conditions for Johnson to push through a Fair Housing Act in 1968.

In foreign policy, Johnson was preoccupied primarily with the United States' protracted postwar effort to contain communism, in which the Vietnam War played a particularly prominent role. This conflict, which pitted North Vietnam and the Viet Cong against the southern Army of the Republic of Vietnam, began prior to Johnson's accession to the presidency. Nevertheless, his administration was responsible for the sizable escalation of U.S. involvement in the struggle. Johnson's war policies faced considerable opposition on the domestic front, especially from draft-age college students. This unrest contributed to Johnson's decision to retire from politics rather than run for a second term in 1968.

The legacy of Johnson's presidency is mixed. His ambitious agenda had many significant implications for the subsequent dynamics and practice of American politics, particularly with regard to the scope of domestic policy and federal-state relations. Nevertheless, the difficulties he faced in negotiating the highly charged social and political atmosphere of the late 1960s cast doubt on the possibility of effective presidential leadership and inaugurated an era of distrust in government.

JONES, EDWARD ELLSWORTH
1926–1993

The American social psychologist Edward Ellsworth Jones earned his AB (1949) and PhD (1953) from Harvard University, both under the direction of Jerome Bruner. He held professorial appointments at Duke University from 1953 to 1977, and was the Stuart Professor of Psychology at Princeton University from 1977 until his untimely death in 1993.

Social psychologists had been interested in the accuracy of interpersonal judgments from the field's inception, but in the 1950s seminal figures such as Solomon Asch and Fritz Heider sparked a new interest in understanding the cognitive processes by which such judgments were made. Heider in particular suggested that ordinary people think of behavior as a product of an actor's enduring dispositions and the situation within which that behavior unfolds, and that a small set of inferential rules allows them to determine to which of these variables an actor's behavior should be attributed on any occasion.

Jones offered social psychology its first formal model of these attributional rules (Jones and Davis 1965). His correspondent inference theory, along with some like-minded theories (e.g., those outlined in Bem 1967, Kelley 1967, and Schachter and Singer 1962), created a sea change in social psychology, and by the early 1970s attribution theory had replaced cognitive dissonance theory as
the field’s premiere theoretical engine. (A full history of attribution theory can be found in Gilbert 1998).

One prediction of correspondent inference theory was that rational observers should not infer dispositions from actions that are performed under extreme duress. But in his experimental work, Jones found that observers do, in fact, infer dispositions under these circumstances (Jones and Harris 1967), and much of his research in the following decades was devoted to exploring the causes and consequences of this “correspondence bias,” or “fundamental attribution error.” His discovery and analysis of this important and robust phenomenon set the stage for the explosion of research in social psychology on biases in human inference that took place in the 1980s.

Having established that observers tend to make a particular kind of mistake when drawing inferences about others, Jones suggested that observers make precisely the opposite mistake when drawing inferences about themselves (Jones and Nisbett 1971). He argued that people tend to think of their own actions as having been controlled by situational forces, but tend to think of others’ actions as expressions of the other’s enduring beliefs, desires, and propensities. His analysis of this “actor-observer effect” implicated perceptual and cognitive factors rather than emotional or motivational factors as the primary sources of what was often a self-serving pattern of inferences, and in so doing, it pioneered a new style of explanation in social psychology.

Jones also argued that if people use attributional rules to draw inferences about others, then they can use these same rules to manipulate the inferences that others draw about them. For example, gratification is a tactic by which actors attempt to make observers like them, and Jones’s early analysis of this phenomenon (Jones 1964) laid the groundwork for his later, more general work on strategic self-presentation (Jones and Pittman 1982). His work on self-handicapping (Berglas and Jones 1978) showed that people sometimes use these tactics to deceive themselves. He summarized much of his thinking on these and other issues in his final book, Interpersonal Perception (1990).

Jones won virtually all the major awards his field could offer, including the American Psychological Association’s Distinguished Scientific Contribution Award in 1977. He was an influential and productive social psychologist who combined a deep insight into human affairs with an unflagging commitment to clear theorizing and experimental investigation. In a half-century of careful and inspiring work, he built a significant part of the foundation on which modern social psychology rests.

JOURNALISM

Journalism is the gathering, writing, editing, photographing, or broadcasting of information through newspapers, magazines, radio, television, or the Internet by any news organization as a business. Just as journalism reports day-to-day news and current affairs, its attributes change with the times. Journalism’s history is closely associated with democracy and business. Not only does journalism derive
its financial strength and power from mass audiences purchasing the product, but it also attains its political strength by swaying the masses. Thus while many may decry the commercialization of information, the mark of success, whether financial or political, is seen in the number of people who access that information and therefore support the endeavor. It is described as the lifeblood of democracy. The intersection between politics and journalism has important and fundamental effects on the stability and legitimacy of democratic regimes.

EARLY JOURNALISM

Newsletters contained news that was written for merchants, businesspeople, and politicians during the seventeenth century. The newsletters exchanged sporadic information about friends abroad or in other colonies between people with common interests. This created an organized circulation, which eventually led to the development of the newspaper.

Pamphlets were published papers that dealt with public questions, while ballads were accounts written in verse. These were distributed in public houses, coffeehouses, and taverns. Such information was printed on broadsides, meaning it was printed on one side of a single sheet. These sheets were sold on the street for a few pence.

Journalism’s popularity and influence in the political process emerged at about the same time as the European discovery and colonization of North America. Johannes Gutenberg (1400–1467) created the first moveable type press in 1455, yet it was not until Christopher Columbus (1451–1506) sailed from Spain in 1492 that the printing press was popularized in Europe. Columbus wrote many letters describing his discoveries of the “Indies.” In 1620, around the time the Mayflower landed at Plymouth, the first “coranto,” or pioneer newspapers, appeared for sale in the streets of London. The first printing press was imported to America in 1639. Over the next forty years, journalism became established in England with the first newspaper, the Weekly News.

In England, the popularization of such materials represented the first clash between government and journalism, with authors and importers of imported books being subject to censorship and harsh prosecutions as well as other impediments, such as high taxes. Undeterred by those punishments, the business of journalism grew. It is estimated that between 1640 and the restoration of the monarchy in 1660, more than 30,000 political pamphlets and newspapers were issued. The beginnings of journalism also coincided with the rise of political parties in England. Political groups realized that if they could get endorsements from newsletters and pamphlets, their interests would be more easily disseminated to the public. This eventually led to the partisan press in both the United Kingdom and America.

The first continuous American newspaper began publishing in Boston on April 24, 1704. It was founded by the city’s postmaster, John Campbell, and was called the Boston News-Letter. It carried news from London journals and focused on English politics and foreign wars. Local content was limited to the arrival of ships, deaths, sermons, political appointments, storms, crimes, and misadventures.

The modern newspaper progressed over the next 200 years, evolving from the broadsheets and pamphlets to weekly sheets and eventually the daily press. Notable figures in the early days of newspapers include Benjamin Franklin (1706–1790), who, with his brother James, published the New England Courant. Seeking new sales, Franklin established the publishing tradition of letters to the editor. Initially Franklin himself wrote letters under pseudonyms to create controversy and arouse interest in his own editorials. The first daily newspapers tended to be highly partisan. This partisan press eventually was replaced by the penny press.

Economies of scale figure prominently in the evolution of newspapers. As presses became larger, the need for greater capital also increased. Those with the most capital were able to secure larger presses and larger audiences, thereby pushing out of business the small, independent producers and creating larger, more standardized formats. The larger scale of the modern newspaper helped develop the craft and techniques of journalism. Tenants of modern journalism are objectivity, the inverted pyramid, and other conventions of standardized writing. The formatting of news in specific ways, such as the inverted pyramid, means that the most important information, the five Ws (who, what, when, where, and why), are placed at the start of the story. This allows readers to find the most important facts quickly. It also means that if the story has to be edited because of space limitations, the last paragraphs are easily cut without losing the main story elements and without the need to rewrite the story.

In addition to movable type, other advances occurred in the creation of the newspaper that influenced the way in which news is reported. The stereotype was invented in 1725 by the Scottish goldsmith William Ged (1690–1749). This consisted of a printing plate of a whole page of type cast in a single mold. These stereotypes were mass produced and were thin enough to be sent through the mails. Large presses purchased the stereotype and sent it to various newspapers. Subscribing newspapers could simply take the stereotype of the news or of cartoons and reproduce them for local readers. The stereotype proved to be so successful that by 1877 nearly eight out of ten newspapers in America provided their readers the same politi-
cal cartoon more cheaply than they could write and set their own. The term stereotype is now used to describe how ideas and public opinion were formed through a consistent message, often one that is simplistic and erroneous.

**NEWSWIRES, THE PENNY PRESS, AND YELLOW JOURNALISM**

As competition increased, so did the need to be the first to break the news. Many technological advances in the nineteenth century facilitated news-gathering competition. These included the steamship, the railroad, and the magazine telegraph. The telegraph proved to be the most efficient means of conveying information over long distances, and the newspaper helped to popularize and ensure its success. While the telegraph was a boon for the speed of news, it was also expensive.

The first newswire, Agence Havas, was started in 1835 by Charles-Louis Havas (1783–1858), considered the father of the press agency. Havas translated material from abroad for the French national press. In 1940 the company was taken over by the state and renamed Agence Française de Presse (AFP). Twelve years later the first North American press agency was created, starting with an agreement between the publishers of the *Journal of Commerce* and the *New York Herald*. In 1848 the Associated Press (AP) was founded at a meeting of ten men representing six New York newspaper publishers. They pooled their efforts in collecting international news. Horace Greeley (1811–1872), the founding editor of the *New York Tribune*, was also a founder of the AP. Having a news wire license would mean a great deal to future newspaper barons because it would ensure their success against competitors who did not have access to the wire. By October 1851 the German-born Paul Julius Reuter (1816–1899) was transmitting stock market quotes between London and Paris over the Calais-Dover cable. His agency, which eventually became known as Reuters, extended its service to the whole British press and to other European countries. Other news wires that emerged were the United Press Association, set up by E. W. Scripps (1854–1926), U.S. Newswire, and Bloomberg, whose focus remains business news. Most countries have some form of newswire service. Newswires helped move newspapers away from partisan declarations. To be a successful news agency, one had to have many subscribing newspapers. The ability to get the story meant stripping the copy of its editorial content and focusing on the facts.

As newspapers became more powerful, their partisan nature extended their impact. Journalism was said to be so powerful that it could elect presidents as well as ruin political careers. One figure who changed the power structure of the partisan press was Joseph Pulitzer (1847–1911), whose career in publishing began inauspiciously with his account of being taken in as a scam artist, written for the *Westliche Post*, a German-language paper in St. Louis, Missouri. After establishing himself, he purchased the *St. Louis Post-Dispatch* at auction for $2,500 (Brian 2001, p. 31). Pulitzer had an inherent sense of social justice, which he brought to his paper. His editorial position was that the *St. Louis Post-Dispatch* would not be a tool of partisan politics. Denis Brian (2001) noted Pulitzer’s pledge: that the paper “opposes all frauds and shams wherever and whatever they are, will advocate principles and ideas rather than prejudices and partisanship” (Brian 2001, p. 32).

Pulitzer is also associated with yellow journalism. Once the *St. Louis Post-Dispatch* was an established and successful paper, he moved to New York and purchased the *New York World*. Within a few years, he took a derelict paper and made it one of the most profitable newspapers in the most competitive U.S. market. To do this he made the paper affordable, cutting the price to 2 cents an issue, and focused on stories that attracted the mass public. Much of this centered on reporting crime and scandal. Later William Randolph Hearst (1863–1951), who admired Pulitzer’s business acumen, copied his success and launched the *New York Journal* to compete against the *World*. The competition for readers between the two New York papers culminated in the dueling Sunday supplements containing the Yellow Kid cartoons, the first cartoons published in color. The *New York Press* editor Ervin Wardman dubbed this competition “yellow journalism,” and the phrase soon became a metaphor for any kind of salacious reporting.

Yellow journalism is the reporting of scandal, divorce, and crime alongside sports. Yellow journalism also refers to false reports, faking of news or interviews, and heavy use of graphic pictures. The battle between Hearst and Pulitzer raged with misleading headlines and each accusing the other of false reports. While the era of yellow journalism reigned from 1892 to 1914, many of its features still linger in contemporary journalism: big headlines, the use of pictures to present information, and the colored comic Sunday supplement.

Despite being associated with the worst of journalism, Pulitzer is also associated with its best. His penchant for accuracy, brevity, and persistence became hallmarks of journalism. While at the time of his death Pulitzer’s estate was in excess of $18 million, he remained interested in the common good. His core journalistic credo was that journalism should never worry about the profits of the owners but rather about telling the truth and uncovering injustice. To this end he provided $2 million for the creation of the Columbia School of Journalism, which opened on September 30, 1912, just under a year after Pulitzer’s death.

While journalism had been big business for some time, the height of its power began at the end of the nine-
teenth century. As the investment in presses became larger, so did the business of journalism and the realization that more money could be made if one owned several small papers rather than one large paper. The person who pioneered this type of capital investment in newspapers was E. W. Scripps, who purchased established papers rather than start new ones. He would choose a city with 50,000 to 100,000 in population and purchase a paper already in operation. Most every year from 1893 until his death, he added nearly a half dozen papers to his holdings. In 1926 the Scripps chain owned thirty-four papers. Hearst too amassed a newspaper empire. The difference was that Hearst established himself in the largest American cities. By the end of 1922 Hearst owned twenty daily papers and eleven Sunday papers in thirteen markets. At his peak Hearst had bought or established forty-two daily papers.

MODERN INNOVATIONS: RADIO, TELEVISION, CABLE, AND THE INTERNET

Newspaper journalism began to wane in popularity as other communication technologies emerged. Radio had a unique ability to transmit wire information directly to the public. This challenged newspapers, which feared they would lose their influence. Initial attempts by newspapers to prevent radio from taking over journalism included blocking radio from receiving newswire stories. Nonetheless, there was little to prevent radio stations from reading the news from competing newspapers. When limiting information to radio did not work, newspapers tried to discredit radio journalism by claiming that radio could not uphold the ideals of objectivity, could not provide public service, or was bad for democracy. All these issues were resolved when AP lifted its ban on radio in 1939, allowing radio to compete with newspapers.

Just as radio challenged and changed the nature of journalism, so too did television news. Not only was information equally available, but television news provided better pictures than newspapers with the timeliness of radio. The focus on images in television news changed the nature of journalism, with images reigning paramount over content. From 1950 to the 1980s television news was the most popular means by which the public received information on current events. Television’s success was in part due to the ease of receiving the information as well as the visual nature of the medium.

The American networks created bureaus in countries around the world and furnished firsthand accounts of history unfolding. While newspapers were severely challenged by radio, both radio and television eventually lost part of their audience. While newspapers declined, they still maintain significant readership. Radio journalism has suffered the most and is used less frequently than other forms of journalism.

Despite the technical innovations of getting the message out, the period between the 1920s and 1970s saw journalists become more routinized and codified in their presentation of material. Journalism schools were created, and the occupation of journalist was elevated from a technical or trade occupation—one that was also low-paying—to a profession characterized by higher education, social status, and eventually pay.

As journalism became more standardized, so too were complaints of perceived bias in the media. Those who supported more government intervention in the economy argued that because journalism is a big business, it focuses on protecting the elites and avoiding stories that might embarrass advertisers. Others, those who supported less government, charged that because journalists were becoming more educated, their views were more in keeping with left-wing intellectuals. At the height of the cold war Senator Joseph McCarthy (1908–1957) led the charge by accusing many prominent journalists (as well as entertainers) of being Communist sympathizers. In particular he took issue with the popular former war correspondent and radio and television journalist Edward R. Murrow (1908–1965) as evidence. Murrow fought back, exposing McCarthy’s false accusations and setting the standard for hard-hitting investigative journalism. His documentary on McCarthy is considered the most famous ever broadcast, and it signaled the end of McCarthyism. When one considers that television news was still in its infancy, with relatively few people having direct access to television, and that it was a program not promoted by the network, it spoke to the potential impact of the medium. That impact was developed during the 1960s and 1970s with domestic events such as race relations and the assassinations of President John F. Kennedy, civil rights leader Martin Luther King Jr., and Senator Robert Kennedy. All these events were given heightened sense of crisis and immediacy in part because television news was able to provide the pictures to go along with the information.

In addition to broadcasting local events in North America as well as Europe, television news could provide pictures from faraway places such as Africa and Southeast Asia. Walter Lippmann’s 1922 depiction of “the world outside and the pictures in our heads” (Lippmann 1922, p. 1) was never more true than with television news broadcasting images from faraway places.

Walter Cronkite, the managing editor and anchor of CBS News from 1962 to 1981, was a trusted and well-respected journalist in part because he maintained the CBS News policy of independent, nonpartisan reporting. Some argue that it was not the continuing pictures and stories of the war from Vietnam that changed the major-
ity view on the conflict but the fact that Cronkite, a former World War II (1939–1945) correspondent, stepped aside from the neutral anchor to present his opinion on the war.

That legacy continued and culminated with the Washington Post’s reporting of a break-in in the Watergate complex in Washington, D.C., in 1972. Relatively junior reporters Bob Woodward and Carl Bernstein are credited with investigating the story in a series of newspaper articles that revealed that the break-in was linked to the Republican Party, whose officials were seeking information about the Democratic Party. President Richard Nixon eventually resigned rather than face impeachment. While many point to the Watergate reporting as the high-water mark for investigative journalism, others argue that the role of journalism in bringing down the president is more myth than fact. Edward Jay Epstein, for example, argues that Woodward and Bernstein were only slightly ahead of the prosecutors and relied on leaked information from the prosecutor’s case. As such, Epstein argues, the information would have come out anyway. It was not Woodward and Bernstein who uncovered the link between the burglars and the White House and traced the illegal activities to the Nixon campaign, it was the FBI. Epstein charges that Woodward and Bernstein “systematically ignored or minimized” the work of law enforcement officials to “focus on those parts” of the story “that were leaked to them” (as quoted in Feldstein 2004, p. 3).

Nixon aide Howard Dean states that the role of the journalists in the Watergate story was not investigative reporting but keeping the story alive long enough to legitimate law enforcement agents who were doing the investigation. The media coverage and subsequent frenzy is what kept the Watergate story in the public eye. The press coverage also helped to keep the public’s interest alive during the televised hearings about the scandal. Ultimately, however, the business of journalism is sustained by the routine gathering of news rather than by investigative journalism. While television became dominant in news gathering and dissemination, the investigative model is ultimately time consuming and expensive. The day-to-day news business is focused on feeding the news cycle with short, easily digested information. As a result investigative articles are more rare than routine.

Only with the emergence of cable news networks did network television news begin its decline. Despite the pressures from other communications technologies, public opinion surveys indicate that local television news remains the most frequent source of information, followed by local newspapers.

Cable news networks challenged traditional television news in several ways. First, providing one service on cable was significantly cheaper than having to supply stations in every market. These savings allowed cable networks such as CNN to establish more bureaus around the world at a time when network television news had to close down bureaus or cut staff. The twenty-four-hour format gave CNN an advantage on stories with great public interest, such as the 1991 Gulf War. CNN not only changed the way international news is covered but also increased interest in and the scope of international affairs on public policy. Thus it is seen as a catalyst for Western governments to intervene in humanitarian crises, subsequently dubbed the “CNN effect.” The extent to which governments react to media coverage of suffering people is debatable, but the public’s awareness of humanitarian crises are much more extensive as a result of the twenty-four-hour news format. By shifting the focus from local topics to international issues, the focus of the public has become more globalized.

The popularization of the Internet has blurred the lines of journalism and public comment. The Internet not only allows for on-demand news, which traditional media have adopted, but it also allows for individuals not normally considered journalists to present their interpretations of current affairs. The Web log, or blog, is a Web site on which individuals write their views on any subject. Blogs have been associated with breaking publication bans, providing critical commentary on accepted journalistic stories, and popularizing certain political interests. Just as challenges to newspapers were discredited as not being proper journalism, traditional journalists also question and try to discredit blogs. The current definition of journalism disavows blog writers in that they do not typically write for commercial interests. The Washington Press Gallery, for example, limits membership by stipulating that to qualify as a journalist, one must be employed by “a periodical that is published for profit and is supported chiefly by advertising or by subscription” (United States House of Representatives, Periodical Press Gallery, Rules and Regulations).

JOURNALS, PROFESSIONAL

There are several means to disseminate ideas, results, experiments, criticism, and discoveries in the sciences and humanities. The most often used are professional journals, books, working papers, technical reports, pamphlets, and presentations at academic conferences. Professional journals are the main means of communication because the majority of journals use the referee or peer-review system for papers submitted for publication. The referee system aims at selecting the best papers and achieving the greatest objectivity possible. In addition, journals provide a fast and efficient way to spread the latest developments in a field of study. They also serve as a forum for discussion, which is essential for the advance of knowledge.

Publications in academic journals are used to rank departments and scholars. Publications are one of the key instruments used to assess the quantity and quality of scholars and departments through objective criteria, a method in line with the belief that scholars and academic institutions should be evaluated on the basis of merit. The ranking of departments and scholars requires a list of journals that are themselves ranked according to their importance. Rankings of journals are based on the relative impact of the papers published. Generally, the impact of a journal is captured by the number of citations to its articles in other journals (Liebowitz and Palmer 1984). An alternative approach to ranking journals is to survey members of the relevant profession (Moulouin and Outreville 1987).

Due to the increase in specialization among and within many branches of the sciences and humanities, the number of specialized journals is increasing. Rajeev Goel and João Faria (2007) showed, in a differential game between editors and authors, that the launching of new journals generates greater competition among editors, enhancing research quality. Another consequence of specialization can be observed in economics, where there has been a fall in the importance of general journals relative to specialized journals (Faria 2002a). In addition, new academic journals have been established as a result of the publication congestion in existing journals. This congestion results from the increasing difficulty of producing high-reputation journals, causing a rise in rejection rates and a time delay between submission, acceptance, and final publication of papers. Glenn Ellison (2002) argues that in economics this slowdown is due to an increasing tendency among journals to require that papers be extensively revised prior to acceptance.

Professional journals are part of the publishing business and thus are subject to market forces. The main agent behind the market performance of academic journals is the publisher. In most cases, a publisher with a good reputation, experience, and penetration in the academic market can make a difference in the performance of an academic journal. In economics, commercial publishers have gained a substantial market share. They have been successful in creating new journals, as well as taking over top journals formerly published by nonprofit organizations, such as professional associations and university presses.

One consequence of the increasing role of commercial publishers in the production of professional journals is a rise in prices. David Rosenbaum and Meng Hua Ye (1997) produced evidence that commercial publishers engage in price discrimination between individual and library subscribers, showing that library prices rise faster than individual subscribers’ prices. Owen Phillips and Lori Phillips (2002) showed that library prices are two to ten times higher than private prices. Nathan Berg (2002) proposed that university libraries, in order to cope with journal-price inflation, pick a threshold level of quality of academic journals below which no subscriptions are ordered.

Plagiarism, rhetorical conventions, and editorial favoritism are among the potential problems that plague professional journals. The majority of the 117 editors of economic journals surveyed by Walter Enders and Gary
Hoover (2004) considered the use of several unattributed sentences to constitute plagiarism. Eighty-three of the 117 editors said that they had seen no cases of plagiarism in a typical year. Of the remainder, twenty-eight editors reported a collective total of forty-two occurrences of plagiarism in an average year. The key findings of Enders and Hoover are that editors tend to rely on copyright law to protect themselves from plagiarism; they are not likely to publicize an instance of plagiarism; and the majority of editors favor a code of ethics enumerating various forms of plagiarism and the appropriate penalties.

Technological innovations change the research tools and may affect the way professionals present their findings. Rhetorical conventions become a problem for journals when professionals put more importance on the presentation of their work than on its content (see McCloskey 1991). Anecdotal evidence suggests, at least in economics, that technical knowledge, such as sophisticated mathematics and econometric techniques, increases the chances for publication. One possible reason lies in the fact that technical knowledge decreases the opportunity cost for a contributor who has acquired the minimal technical expertise demanded by the journal (Wallis and Dollery 1993); in addition, technical knowledge makes it easier for a referee to evaluate an article. As stressed by Bruno Frey (2001), the emphasis on formalism may lead to a disregard for relevance and originality.

Editorial favoritism is a serious problem for professional journals because it can be a significant source of bias in the evolution of knowledge. The bias is mainly reflected in the choice of topics, research techniques, and literature. Editors and referees may choose to publish a paper not because of its content but because of the author’s network of connections or his or her views. David Laband and Michael Piette (1994) point out that editorial favoritism generates sizable wealth redistributions among members of the scientific community, providing strong incentives for authors to attempt to influence their chances of publication and citation. Of course, academic networks facilitate the circulation of ideas and personal contacts, which are essential to fostering the advance of knowledge (Faria 2002b). In the same vein, editors, following Thomas Kuhn (1962), may be interested in defending the prevalence of and reinforcing a given paradigm. However, in spite of the difficulty in investigating the fundamentals of editorial bias (Medoff 2004), the possibility of its occurrence raises a red flag on the dangers of exogenous factors interfering with the process of knowledge formation.

### JUÁREZ, BENITO

1806–1872

In twentieth-century Mexico, no name was used more frequently to name streets, public buildings, and towns than that of Benito Juárez. A Zapotec Indian lawyer from the southern state of Oaxaca, Juárez stood at the helm of the liberal, reformist republican project during the bloody nineteenth-century civil war against the conservatives,
which became a struggle against a monarchical regime supported by French military intervention (1858–1867). He then presided over the restoration of the republic and governed, until his death, under the heavy criticism of the opposition in Congress and an exceptionally free press. One of nineteenth-century Mexico’s ablest politicians, he became, within a generation of his death, one of the nationalist imagination’s most enduring symbols. His life story opens a window on the complex workings of politics in nineteenth-century Mexico at a critical juncture, and the recurrent reconstruction of his image as a national symbol offers clues to the transformations of Mexican political culture.

Juárez left the monolingual Zapotec community of San Pablo Guelatao as a twelve-year-old who spoke little Spanish (he would later be able to read Latin, English, and French) to join his sister, a house servant, in the state capital city of Oaxaca. He studied law at the city’s seminary and then at its secular, modern Institute of Arts and Sciences. In a state where liberalism had a broader, more popular appeal than in other regions, Juárez entered politics early and gained experience at all levels of government. He was a member of the Oaxaca city council and of the local and then the federal Congress. He was also a judge, prosecutor, secretary of state, and governor. Nevertheless, his promising political career was interrupted, like that of many young politicians in the provinces, by the dictatorship, from 1853 to 1855, of military strongman Antonio López de Santa Anna (1794–1876), which sought to put an end to representative politics and state autonomy. Juárez was exiled and ended up in New Orleans, Louisiana, where his perspectives were broadened and his political vision sharpened through contacts with more sophisticated Mexican radicals like Melchor Ocampo, Ponciano Arriaga, and José María Mata.

The fall of Santa Anna brought about a new era in Mexican politics that was known as the Reform (1855–1867). Despite differences among them, the young provincial liberals who arrived on the national stage in 1855—among whom Juárez would cut an elder-statesman figure—were committed to modernizing Mexico through the restoration of federalism, the strengthening of the national government, and the destruction of those “vices” that were the legacy of colonial times: corporate privilege, which denied equality before the law; corporate ownership of land, which made for a sluggish economy; and the overwhelming power of the Church. Their project was given expression in the 1857 constitution, which prevailed after ten years of armed struggle. The first conflict (1858–1860) was against the conservatives, who feared that the constitution’s attack on the Church and religion would tear apart the deteriorated social and moral fabric of Mexican society. The struggle next included Napoléon III’s army, who joined the conservative cause and sought to establish a French-sponsored empire led by Austrian archduke Maximilian, who served as emperor of Mexico from 1864 to 1867. Unlike the four constitutions that preceded it, that of 1857 provided a stable, if not always heeded, juridical framework over the course of half a century.

Juárez, as minister of justice, drafted the 1855 law that put an end to ecclesiastical and military judicial privilege in civil suits. Although he did not participate in the design of the constitution, having been reelected governor of his home state, it became his touchstone and source of legitimacy as he assumed the presidency in 1858 after a conservative coup d’état. When the coup set up a government that abrogated the constitution in the nation’s capital, Juárez set up the constitutional government in Veracruz. The country was effectively divided in two. For Juárez, the constitution stood for putting the rule of law above petty rivalries, politically convenient shortcuts, and regional interests. The Reform laws promulgated by Juárez in 1859 and 1860 greatly diminished the power of the Church by nationalizing ecclesiastical wealth, shutting down religious orders, establishing a civil registry, and formalizing religious freedom. It was his insistence on adherence to the constitution that consolidated his legitimate leadership as a civilian president over the military. It provided the principles through which he tried to solve one of the national government’s most pervasive problems since independence: its recurrent altercations with the states, particularly over men and money. On the other hand, he did not consider constitutional principle a strict mandate for government action. Like all presidents who governed under the 1857 law, he repeatedly asked Congress for emergency powers. In 1865, when his presidential period ran out, he refused to step down, alleging that the war made holding new elections impossible. When in 1867 he tried and failed to amend the constitution, he appealed directly to the electorate instead of following the constitutionally mandated process for reform.

After leading the country in what was then called the second war of independence, Juárez won two contested reelections, carried by a political machine that relied on the federal bureaucracy. He died as president in 1872, having secured the principle of constitutional rule; until 1917, challenges to political authority were articulated in defense of the constitution, never again against it. But if the constitution was consecrated as a national symbol and as the structure for political struggle, it failed to set up the mechanics for some crucial aspects of government, particularly for the transmission of power through elections. This is attested by the two rebellions led by Porfirio Díaz (1830–1915), one called the Plan de la Noria in 1871, the other called the Plan de Tuxtepec in 1876. Additionally, the Reform’s disentitlement of communal lands and the
nationalization of Church wealth did not bring about the prosperous nation of farmers that the liberals envisioned, but often the concentration of land ownership and the discontent of Indian communities.

Juárez’s performance as a politician and statesman was controversial. Nevertheless, his transformation into an icon preceded his death: In the 1860s, other Latin American countries hailed him as a symbol of successful resistance to European imperialism. Once dead, Juárez, as Charles Weeks writes in his book *The Juárez Myth in Mexico* (1987, p. 42), “was far more valuable to all” as a particularly powerful and pliable symbol. In the 1890s orthodox liberals, despairing of Porfirio Díaz’s authoritarian ways and his rapprochement to the Church, upheld Juárez as a symbol of true liberalism betrayed. Díaz ably took this banner away from them by claiming to be Juárez’s true heir and throwing the weight and resources of government behind the juarista cult. In 1904 Francisco Bulnes (1847–1924), a prominent Porfirián politician, wrote a scathing critique of Juárez’s actions during the French intervention and of the nationalist narrative that he believed was reducing history to hagiography. He unleashed a furious reaction from both Porfirián intellectuals and their opposition, and his criticism of Juárez was taken as an attack on the nation.

The Bulnes controversy sets the tone for the use and abuse of Juárez’s figure as a source of legitimacy throughout the twentieth century as the self-proclaimed revolutionary state took up the mantle of nineteenth-century liberalism. References to Juárez in official rhetoric have been inevitable, especially from the mid-1940s, with the consolidation of civilian government and with the increasing importance of stability and economic growth over reform. He has personified administrative honesty, the secular state (despite his moderation and good relations with the Church in Oaxaca), strict adherence to law (although he violated the letter of the constitution), the defense of national sovereignty (although he authorized the signing of the unfavorable McLane-Ocampo treaty with the United States in 1859), and indigenism (even though he did not speak of “Indian rights” and repressed Che Gorio Melendre’s movement to defend community resources in Juchitán in 1850). To the opposition right, on the contrary, he has been the embodiment of treachery to the true (Catholic) nation. Allusions to Juárez, then, are not meant to refer to historical experience or to policy content; they intend to draw the line between good and evil, patriotism and treason. Juárez has arguably been more important for what he has represented than for what he did.

**JUDAISM**

Judaism is the religion founded upon the Hebrew Scriptures, or “Old Testament,” which is viewed as an exhaustive account of God’s will for humanity. Judaism is the oldest of the three monotheist religions—the others being Christianity and Islam. The Hebrew scriptures first took shape around 450 BCE with the assembling of the Torah (“instruction”), which recorded the revelation of God to Moses at Mount Sinai. The Torah is composed of the Five Books of Moses: Genesis, Exodus, Leviticus, Numbers, and Deuteronomy. The sacred Scripture also encompasses the Prophets: Joshua, Judges, Samuel, and Kings, Isaiah, Jeremiah, and Ezekiel, and the twelve minor prophets; as well as the Writings: Psalms, Proverbs, Job, Ecclesiastes, Lamentations, Song of Songs, Ruth, Esther, Daniel, Chronicles, and Ezra-Nehemiah.

The Torah and the Prophets tell twin stories of exile from Paradise—one concerned with humanity as a whole, the other with Israel, the people of the Torah. Adam and Eve, representing humanity, lose Paradise—the Garden of Eden—because of their rebellion against God. The people of Israel likewise lose their paradise—the Land of Israel—because of their disregard of God’s will as revealed in the Torah. Israel had acquired the Promised Land in fulfillment of God’s covenant with Israel’s founders, Abraham and Sarah, and their descendants. In 722 BCE, however, the northern kingdom of Israel fell to the Assyrians and was incorporated into Assyria, and in 586 BCE the southern kingdom of Judea fell to the Babylonians, who destroyed the Temple of Jerusalem. Following this, the Jews went into exile in Babylonia (present-day Iraq). In the later sixth century BCE the Babylonians were conquered by the Persians, who in 530 permitted the exiled Judeans to return to Jerusalem and rebuild the Temple there on Mount Zion. Some did just that. Then, around 450 BCE the scribe Ezra, in cooperation with the Temple
priests, promulgated the Torah of Moses as the law for Israel.

The Torah portrays Israel's exile as the consequence of rebellion and its return as its reward for repentance, and sets forth the rules that Israel must keep if it is to retain paradise in the Land of Israel. The parallel narratives—the stories of Adam and Eve and their counterpart, the people of Israel—part ways with the return to Zion, for whereas Israel could repent and reform, Adam, representing the rest of humanity, without the Torah could do nothing to regain Paradise.

THEOLOGY OF JUDAISM

The theology of Judaism is set forth by the rabbis of the first six centuries CE in their readings of Scripture. These readings took place in dialogue with a set of documents that record the oral traditions that had been passed on via a chain of masters and disciples stretching back to Moses and up to the early centuries of the Common Era. The first of these documents recoding oral tradition is the Mishnah (ca. 200 CE), a law code that both amplifies the laws of Scripture and sets forth laws that take up topics not treated by Scripture. A collection of supplements, the Tosefta (ca. 300 CE), and two commentaries to the Mishnah, the Talmud of the Land of Israel (ca. 400 CE) and the Talmud of Babylonia (ca. 600 CE), augmented the laws of Scripture as systematized in the Mishnah's topical expositions. The same rabbis produced commentaries on Scripture, called Midrashim: among others, Genesis Rabbah (ca. 400), on Genesis; Mekhila Attributed to Rabbi Ishmael (ca. 300), on Exodus; Leviticus Rabbah (ca. 450), on Leviticus; and Sifré to Numbers and Sifré to Deuteronomy, on Numbers and Deuteronomy, respectively.

The monotheism of Judaic theology as set forth in Scripture and oral tradition contrasts strongly with the polytheism prevalent at the time of Judaism's foundation. For a religion of numerous gods, life's problems have many causes; for a religion of only one God, there is only one cause. To explain why life is seldom fair and often unpredictable, polytheism identifies multiple causes, one god per anomaly. Diverse gods do diverse things, so it stands to reason that the outcomes of their actions conflict. Monotheism by its nature explains many things in a single way. One God rules all and everywhere. Life is meant to be fair, and just rules are supposed to describe what is ordinary, all in the name of that one-and-only God. Thus, in Judaic monotheism a simple logic governs, to limit ways of making sense of things. But that logic contains its own dialectics. If one true God has done everything, then, because he is God all-powerful and omniscient, all things are credited to, and blamed on, him. In that case he can be either good or bad, just or unjust—but not both.

Jewish theology attempts to systematically reveal the justice of the one-and-only God of all creation. God is not only God but also good. The Torah pictures a world order based on God's justice and equity. Judaism finds its dynamic in the struggle between God's plan for creation—to create a perfect world of justice—and man's will. That dialectic is embodied in a single paradigm: the story of Paradise lost and regained.

Four key sets of beliefs characterize the theology of Judaism:

1. God formed creation in accord with a plan, which the Torah reveals. The facts of nature and society set forth in that plan conform to a pattern of reason based on justice and together constitute God's world order. Private life as much as public order conforms to the principle that God rules justly in a creation of perfection. Those who possess the Torah—namely, Israel—know God and those who do not—the gentiles—reject him in favor of idols. What happens to these two sectors of humanity, respectively, corresponds to their relationship with God. Israel in the present age is subordinate to the nations, because God has designated the gentiles as the medium for penalizing Israel for its rebellion—meaning that Israel's subordination and exile is intended to provoke repentance.

2. The perfection of creation, realized in the rule of exact justice, is signified by the timelessness of the world of human affairs, and its conformity to a few enduring paradigms that transcend change. Perfection is further embodied in the unchanging relationships of the social commonwealth, which assure that scarce resources, once allocated, remain unchanged. Further indications of perfection lie in the complementarity of the components of creation, and in the correspondence between God and man, who was created in God's image.

3. Israel's condition, public and personal, constitutes flaws in creation. What disrupts perfection is the sole power capable of standing on its own against God: man's will. What man controls and God cannot coerce is man's capacity to form intention and therefore choose either arrogantly to defy, or humbly to love, God. Because man defies God, the sin that results from man's rebellion flaws creation and disrupts world order. As with Adam and Eve's exile from Eden, the act of arrogant rebellion leads to humanity's flawed condition. God retains the power to encourage repentance through punishing man's arrogance. In mercy, moreover, God exercises
the power to respond to repentance with forgiveness—that is, a change of attitude bringing about a change in man's condition. Because man also has the power to initiate the process of reconciliation with God through repentance—an act of humility—man may restore the perfection of that order his arrogance has marred.

4. God ultimately will restore that perfection that embodied his plan for creation. In the process of restoration, death—which exists because of sin—will die, the dead will be raised and judged for their deeds, and most, having been justified, will go on to eternal life in the world to come. The paradigm of man restored to Eden is realized in Israel's return to the Land of Israel. In that world or age to come, idolaters will perish, and the remaining portion of humanity, comprising Israel, will know the one, true God and spend eternity in his light.

JUDAISM AND PHILOSOPHY:
MEDIEVAL RATIONALISM

The theology of Judaic monotheism set forth by the rabbis of the first six centuries CE was subsequently amplified by philosophers and mystics. Judaic intellectuals in the Islamic world, from the advent of the Prophet Muhammad in the seventh century CE, faced the challenge posed by Muslim rationalism and philosophical rigor. The task at hand was to reconcile and accommodate Torah and the philosophical form of science.

That is why alongside the study of Torah—meaning the Babylonian Talmud and later codes, commentaries, and rabbinical court decisions—a different sort of intellectual-religious life flourished in Judaism. This was the study of the Torah-tradition through the instruments of reason and the discipline of philosophy: the quest for generalization, a critical sifting of evidence, and, above all, the attempt to find harmony between the generalizations of the Torah and the scientific principles of Aristotle. For example, how can the scriptural notion that God changes his mind be harmonized with the Aristotelian principle that change indicates imperfection, and how can the belief that miracles interrupt the course of nature be reconciled with the philosophical principle that laws of nature are immutable? If God is arbitrary, then God is no philosopher. But for Judaic, Christian, and Islamic theology, God is the source of all truth, whether revealed in nature or in scripture.

The Judaic philosopher had to cope with problems imposed not only by the Torah's conflict with philosophy, but also by the anomalous situation of the Jews themselves. For instance, what was the meaning of the unfortunate history of the Jews? How was philosophy to account reasonably for the homelessness of God's people, who were well aware that they lived as a minority among powerful, prosperous majorities—Christian or Muslim? If the Torah were true, why did different revelations claiming to be based upon it—and to complete it—flourish, while the people of Torah suffered? Why, indeed, ought one to remain a Jew, when every day one was confronted by the success of the daughter religions? Conversion was always a possibility—an inviting one even under the best of circumstances—for a member of a despised minority.

The search was complicated by the formidable appeal of Greek philosophy to medieval Christian and Islamic civilizations, two cultures in which Judaism was practiced. Its rationalism, openness, and search for pure knowledge challenged all revelations. Philosophy called into question all assertions based not on reason, but on appeals to a source of truth not universally recognized. Specific propositions of faith and the assertions of holy books had to be measured against the results of reason. Belief in mysterious divine plans conflicted with claims for the limitless capacity of human reason. It seemed, therefore, that reason stood in opposition to revelation, and free inquiry could not be relied on to lead to the synagogue, church, or mosque. Faith or reason—this seemed to be the choice.

For the Jews, moreover, the very substance of faith—in a personal, highly anthropomorphic God who exhibited traits of character not always in conformity with humanity's highest ideals and who in rabbinic hands looked much like the rabbi himself—posed a formidable obstacle. The obvious contradictions between belief in free will and belief in divine providence further enriched classical philosophical conundrums. Is God all-knowing? Then how can people be held responsible for what they do? Is God perfect? Then how can he change his mind or set aside his laws to forgive people? No theologian in such a cosmopolitan, rational age could begin with an assertion of a double truth or a private, relative one. The notion that something could be true for one party and not for another, that faith and reason were equally valid and yet contradictory were ideas that had little appeal.

JUDAISM AND THE OTHER MONOTHEISTIC RELIGIONS

From the time of the Roman emperor Constantine, who in the fourth century declared Christianity legal and whose heirs made it the religion of the Roman Empire, to the nineteenth century, Jewry in Christendom had sustained itself as a recognized and ordinarily tolerated minority. The contradictory doctrines of Christianity—which saw Jews as Christ-killers to be punished, and as witnesses to be kept alive and ultimately converted at the second coming of Christ—held together in an uneasy balance. Official policy—keep the Jews alive, but do not
reward their disloyalty—accounts for the Jews’ survival in some of the Christian realms, particularly those on the frontiers of Christian Europe, south and east. The pluralistic character of some multiethnic societies explains the welcome accorded Jewish entrepreneurs in certain territories, including Spain before 1492, and Norman England, Lithuania, Poland, Russia, and Ukraine in the early centuries of their development.

The rabbinic system, for its part, had addressed the agenda of Christianity and for long centuries had given answers that, for Israel, proved self-evidently valid. Judaism had answered the question made urgent by Christianity’s triumph: What is Israel in the divine plan? This it did by appeal to the sanctification of Israel and its future salvation. Normative Judaism had taken shape in response to the challenge of Christianity. So long as in Christian lands Christianity defined the issues, Judaism would flourish without effective competition within Jewry, absorbing and accommodating new ideas. The same was true of Islamic lands and the character of Judaism in the Muslim world.

**JUDAISM AND MODERNITY**

In modern times, faced with the political changes brought about by the American Constitution of 1787 and the French Revolution of 1789, Jews in western Europe and the United States aspired to rights possessed by the majority population: citizenship, equality before the law. But an urgent question emerged: How could and why should one be both Jewish and German or Jewish and French or Jewish and British? (The issue was conceived in terms of the categories of religion and nationality; that is, Jews were Jewish by religion and German by nationality. In the late-twentieth-century United States the issue would be conceived in terms of religion and ethnicity; thus, one could be both Christian and ethnically Jewish.) From the earliest decades of the nineteenth century, new Judaisms took shape, dealing with this and other urgent questions. They offered explanations of how a Jew could be not solely an Israelite but also something—anything—else. To do so, people had to identify a neutral realm in the life of individuals and consequently of the community, a realm left untouched by the processes of sanctification leading to salvation, which had for so long made Jews into “Israel,” the community of Judaism. Each of these Judaisms claimed to continue in linear succession the Judaism that had flourished for so long, to develop it incrementally, and so to connect, through the long past, to Sinai. But in fact, each one responded to contemporary issues deemed urgent among one or another group of Jews.

**THE REFORM, ORTHODOX, AND CONSERVATIVE JUDAIC RELIGIOUS SYSTEMS**

Three main new Judaisms took shape between 1800 and 1850. The first to emerge was Reform Judaism, which developed in the early part of the nineteenth century. Reform Judaism made changes in liturgy, then in doctrine and in the Jewish way of life. More significantly, perhaps, it recognized the legitimacy of making changes and regarded change as reform—hence its name.

Second to develop was Orthodox Judaism, which achieved its first systematic expression in the middle of the nineteenth century. A reaction to Reform Judaism, Orthodox Judaism was in many ways continuous with traditional Judaism, but in other ways it was as selective in its adoption of elements of traditional Judaism as was Reform Judaism. Orthodox Judaism denied the validity of change, and held that Judaism lies beyond history; it is the work of God, and constitutes a set of facts of the same order as the facts of nature. Hence change is not reform, and Reform Judaism is not Judaism. But, at the same time, Orthodox Judaism affirmed that one could devote time to science as well as Torah-study, an accommodation with contemporary culture different only in degree from the Reform compromise.

Third in line and somewhat after Orthodox Judaism came positive Historical Judaism, known in America as Conservative Judaism, which occupied a middle position between the two other new Judaisms. This Judaism maintained that change could become reform, but only in accordance with the principles by which legitimate change may be separated from illegitimate change. Conservative Judaism would discover those principles through historical study. In an age in which historical facts were taken to represent theological truths, the historicism of Conservative Judaism gave it compelling weight. Positivism and dependence on history to validate theological conviction would serve Conservative Judaism poorly later on, however, when the discoveries of archaeologists called into doubt principal parts of the scriptural narrative.

JUDICIAL REVIEW

Judicial review is the legal principle that recognizes the power of courts to declare an act of Congress or the president unconstitutional. This power was most firmly established in the 1803 U.S. Supreme Court case of Marbury v. Madison. In a larger sense, the case exemplifies the uncertainties of litigation and how law evolves in a democratic form of government. It was the uncertainty embedded in litigation that prompted Supreme Court Justice Oliver Wendell Holmes (1841–1945) to declare that the object of the law is prediction when he stated that: “the prophecies of what the courts will do in fact, and nothing more pretentious are what I mean by the law” (1897, p. 461). In the American judicial system, what courts will do in fact about legal controversies brought before them will necessarily differ and possibly evolve from one case to another depending upon the facts and circumstances surrounding each case. Although the Framers conceived of the judiciary as the “least dangerous branch” insofar as the constitutional rights of the people are concerned, many now believe that this claim no longer rings true because they see the Supreme Court as the most powerful of the three stations of constitutional power in U.S. government. For the most part, the Court owes its current power and high status to the principle of judicial review.

The story of the origin of modern judicial review started in earnest with the presidential election of 1800 between the incumbent president John Adams (1735–1826) and the challenger Thomas Jefferson (1743–1826). That contest produced no clear winner after all Electoral College votes were counted. In that situation, the U.S. Constitution requires the House of Representatives to settle the election by choosing the president and vice president. During the month of February 1801, after much debate in Congress, Thomas Jefferson was selected president and Aaron Burr (1756–1836) vice president. Because the Federalist Party (the modern-day Democratic Party) had lost control of Congress and the presidency, the outgoing president, John Adams, proposed and Congress approved the Circuit Court Act of 1801, which authorized six new circuit courts and several district courts to accommodate the new states of Kentucky, Tennessee, and Vermont. This bill guaranteed the Federalists temporary control over the judiciary. During his final six months in office, John Adams submitted well over two hundred nominations to Congress, with sixteen judgeships approved by the Senate during his last two weeks in office.

One of the most important developments that took place during this transition period was that Federalist Oliver Ellsworth (1795–1800) resigned his position as chief justice of the Supreme Court, giving Adams an opportunity to name a Federalist successor. Adams immediately turned to former Chief Justice John Jay (1745–1829), who had resigned to become the governor of New York. Jay refused to return to the center chair. Then Adams turned to his secretary of state, John Marshall (1755–1835). Marshall accepted the appointment and was quickly confirmed by the Senate in January 1801 while he was still serving as secretary of state.

In addition to the Circuit Court Act, the Federalist Congress enacted the Organic Act, authorizing the president to appoint forty-two justices of the peace in the District of Columbia. The men Adams chose to fill these positions were called “midnight appointees,” and virtually all were Federalists. It is noteworthy that this seemingly trivial act would set the stage for the most dramatic event that led to the Court’s decision in Marbury v. Madison, the case that firmly established the doctrine of judicial review.

During the last days of John Adams’s administration, there was a sudden rush to clean house in preparation for the new administration’s arrival. As a result, Secretary of State John Marshall neglected to deliver some of the commissions for justice of the peace. If he had not neglected this duty, the ensuing controversy would have been avoided. One of these commissions belonged to William Marbury, a resident of the District of Columbia. When the new administration assumed power, Thomas Jefferson was displeased with his predecessor’s blatant effort to pack the judiciary with Federalist loyalists. Therefore, he ordered his secretary of state, James Madison (1751–1836), not to deliver the commissions. Determined to obtain their commissions, Marbury and three others went directly to the Supreme Court. They invoked the Court’s original jurisdiction powers and requested a writ of mandamus, which is an order that would require a government official (in this case, the secretary of state) to perform a government function (e.g., deliver the commissions). The case was placed on the Court’s docket for the 1802 term. But while the case was pending, the new Republican majority in Congress decided to eliminate the entire 1802 Supreme Court term out of anger toward the actions of a lame-duck
president, and so the decision in Marbury v. Madison was postponed until February 24, 1803.

This case presented John Marshall and the Supreme Court with a daunting predicament. Should the Supreme Court issue the writ of mandamus? What if the writ were issued and President Jefferson (through his secretary of state) refused to honor it? These were important questions requiring careful deliberation. Certainly the potential institutional consequences for the Supreme Court could be disastrous if the Court made the wrong choice. The balance of power in the government would be dramatically altered and the Court would suffer further diminished influence in the current and future affairs of government. Worse still, Jefferson and subsequent presidents could play fast and loose with the Constitution by assuming an inherit authority to act as they pleased without the watchful eye of the Court.

One can think of this case as a game of strategy. Both the Court and the president had real choices to make and each choice presented a real consequence. Since the Supreme Court had to make a decision after receiving the case, it got to move first in the game. The Court had to decide whether to issue the writ or not. If the Court chose to issue the writ, President Jefferson would probably choose not to honor it, precipitating a constitutional crisis. In this outcome, the Court would be severely weakened since it would lack the power to enforce its own decisions. If Jefferson honored the writ, however, that choice would be viewed as an embarrassing defeat for him and his administration. His power of persuasion would be damaged. Neither of these two possible scenarios—the Court’s choices or the president’s—sounded promising.

If, on the other hand, the Supreme Court failed to issue the writ, it would be viewed as weak by members of the Federalist Party in Congress and Marshall’s reputation within the party would be severely tarnished. The remaining decisional choice was for the Court to declare the law authorizing William Marbury's legal request unconstitutional. The Court settled for this option, thereby avoiding a constitutional confrontation with the president. By declaring a federal law null and void for the first time, the Supreme Court firmly ushered in judicial review and sent a clear message that it stood ready to assert itself as an independent and coequal branch of the federal government. Historians of the Marbury affair consider the Court’s decision something of sheer genius, although by all practical purposes it is possible that both the Supreme Court and the president were merely reacting rationally based upon information available to them.

How did John Marshall and the Supreme Court reach that decision? Analysis of the opinion suggests that the Court addressed three interrelated questions raised in the case. First, was William Marbury legally entitled to the commission? The Court answered yes, noting that the commission was indeed signed by the president; hence the appointment was made and it was completed when the secretary of state affixed a seal of the United States. Marbury therefore suffered a legal injury and as a matter of right was entitled to the commission. Second, did the law afford Marbury a remedy for his claim? Yes. Failing to offer Marbury an appropriate remedy would amount to a plain violation of his right under the Constitution. Finally, was that remedy a mandamus issued by the Supreme Court? The Court said no. Even though the Judiciary Act of 1789 authorized the Court to issue a writ of mandamus to “persons holding office, under the authority of the United States,” the Court lacked the proper jurisdiction to issue a writ of mandamus because Section 13 of that Act provides an unconstitutional grant of original powers to the Supreme Court. Article III of the U.S. Constitution specifies in full the original jurisdiction powers of the Supreme Court. To alter that constitutional grant of power requires a constitutional amendment, not a congressional statute.

Judged under proper standards of ethical behavior, it seems that Marshall should have exempted himself from participating in this case since his own absent-mindedness precipitated the conflict in the first place. Although the law creating the vacancies for justice of the peace was later repealed by the anti-Federalist Congress, its legacy has lived and will continue to live on for generations to come.

The significance of Marbury v. Madison is that it declared an act of Congress unconstitutional, thereby affirming judicial review and independence. But the idea of judicial review itself was neither new nor born in that case. For instance, in 1795, eight years before the Marbury decision came down, there was a glimpse of the Court’s thinking on the issue of judicial review in the case of Van Horne’s Lessee v. Dorrance. In that case, Justice William Paterson (1745–1806) explained that in the American form of government, the “Constitution is the sun of the political system, around which all Legislative, Executive, and Judicial bodies must revolve. Whatever may be the case in other countries, yet in this there can be no doubt, that every act of the Legislature, repugnant to the Constitution, is absolutely void” (The Supreme Court of the United States 1992, p. 18). It was the principle elegantly expressed by Justice Paterson that Marbury v. Madison confirmed and later institutionalized as the most wide-ranging grant of power to the American judiciary.

Since Marbury’s decision came down, the Supreme Court has relied on its power of judicial review to redefine the institutional relationships between the three branches of government, as well as the power-sharing relationships between the states and federal government. Most observers think judicial review has been a success. And
this can be seen in part by the adoption of judicial review by emerging and even well-established democracies. In 2004, for example, an independent judiciary with the power of judicial review in Ukraine nullified a widely perceived fraudulent presidential election. In South Africa, Ecuador, and many other young democracies, judicial review has been adopted as an institutional reform to bring about a sense of permanence and stability to their governments. Clearly, these countries have seen the benefits of judicial review in the United States and other established democracies, such as Germany, Japan, and Spain.

JUDICIARY

The judiciary is the branch of government charged with resolving, or adjudicating, disputes between citizens, between other government institutions, and between the government and its people. Judicial power may extend to three separate functions: (1) administering the criminal justice system by determining when a violation of the criminal law has occurred and declaring the appropriate sanction for that violation; (2) administering the civil justice system by resolving disputes, enforcing contractual obligations, and protecting property rights; and (3) exercising judicial review of legislative enactments to ensure that new laws comport with constitutional requirements.

The disputes resolved by judicial entities—often called courts or tribunals—are referred to as cases. Courts may rest the authority to resolve a case in a single official, who may be called a magistrate, a judge, or a justice. In the alternative, some courts, called collegial courts, place decision-making authority in a group. In a collegial court, a group of judges will hear a single case and will collectively be responsible for adjudicating its outcome.

The scope of a court’s authority is its jurisdiction. Jurisdiction may be defined geographically, with a judicial entity having authority over a particular city, state, or region. In the alternative—or additionally—a court’s jurisdiction may be defined by subject matter. For example, a court may have authority only over issues of intellectual property or only over issues of criminal law; such a court would be a court of limited jurisdiction, as opposed to a court of general jurisdiction.

Finally, a court’s jurisdiction may be original or appellate in nature. A court’s original jurisdiction extends to those cases it hears before any other court. In contrast, a court’s appellate jurisdiction extends to cases in which it is reviewing the decision of another court. The notion of appellate jurisdiction presupposes a hierarchical judicial system.

For example, in the United States, each state has its own judicial system, and the federal government has a separate—more appropriately, a parallel—judicial system. The federal judiciary is hierarchical: federal district courts, which have original jurisdiction in most disputes, have jurisdiction over a set geographic territory, no larger than a state; U.S. circuit courts of appeals, which function as intermediate appellate courts, also have jurisdiction over a set geographic territory, usually a group of contiguous states; and the U.S. Supreme Court is a single judicial body that has jurisdiction over the entire nation.

The U.S. Supreme Court primarily exercises appellate jurisdiction, reviewing decisions of lower federal courts and state high courts; a citizen involved in a dispute with his neighbor cannot go directly to the U.S. Supreme Court but, rather, can only appeal to the U.S. Supreme Court after attempting to obtain a favorable verdict from at least one lower court, and usually several. The U.S. Constitution, however, carves out a few types of cases, such as cases involving foreign officials, over which the Supreme Court has original jurisdiction; accordingly, such a case could begin and end in the Supreme Court, with no other judicial body ever rendering a decision.

COMMON PRINCIPLES

Although judicial systems vary significantly from nation to nation—and even sometimes from jurisdiction to jurisdiction within a single nation—there are a few aspirational characteristics that most judicial bodies share. Among these ideals are objectivity and institutional independence.

Objectivity The rule of law is a cornerstone of government legitimacy, particularly in democratic states. The judiciary is the voice of the law, and in a just society the application
of the law is not affected by favoritism or bias. Accordingly, an ideal judicial system is objective.

Judicial officials are expected to leave their personal preferences out of their decision making, and institutional rules are often designed to eliminate or minimize the possibility, even the appearance, that judges are motivated by anything other than the law. In an effort to expose potential bias, judges frequently must disclose their financial records, and in systems where judges are elected, rules relating to campaign contributions may be especially stringent. Many judicial systems provide rules against ex parte communication—communication about a case with one party or attorney to which the other party or attorney is not privy—and rules against the judge discussing the case with the public or media before an official decision has been rendered. Ultimately, the goal of all of these rules is to eliminate any personal interest in the outcome of the case and to limit the ability of outside parties to sway the judge’s position.

Of course, like every government institution, the judiciary is composed of human beings who cannot leave their humanity at the door. Most judges have studied the law, perhaps worked as attorneys or held other public office, and are generally well-informed individuals. It would be bizarre to expect that they do not have opinions about legal issues, judicial philosophy, and public policy. Moreover, it would be unreasonable to expect that judges can compartmentalize their own opinions to such an extent that they have no effect whatsoever on their judicial decisions.

Studies of judicial behavior, primarily of justices on the U.S. Supreme Court, have persuasively demonstrated that judicial decisions are affected to some extent by ideological concerns. Specifically, to the extent that Supreme Court justices disagree about the outcome of a particular case—an indication that the law is not entirely clear—there are predictable patterns of agreement between the justices and predictable patterns of voting that correspond, roughly, to liberal and conservative viewpoints. There is considerable debate about the conditions under which and the degree to which ideology colors judicial decision-making, but it is generally accepted that ideology is a factor. Indeed, decisions about selecting and electing judges in the United States are highly politically charged because it is generally understood that judges bring their individuality to the task of judging and are not, rather, automatons rigidly applying the law.

Institutional Independence To protect the rule of law, judicial officials must be objective; the influence of their personal preferences, biases, and interests on their decisions should be minimal. Yet it is not enough to constrain the members of the judiciary; they must also be protected from threats of reprisal from unpopular decisions. Thus, another common ideal for judicial institutions is that they enjoy institutional independence.

Referring to a government institution as a judiciary generally distinguishes it from a legislature (a deliberative body that develops laws and policies) or an executive (the individual or individuals charged with carrying out the will of the government). The judicial power, however, is not always severed from the legislative and executive powers. For example, the biblical King Solomon was renowned for his ability to resolve disputes, and in the English feudal system of the Middle Ages, landowners adjudicated disputes among their tenants. Similarly, many Native American tribes traditionally vested the authority to resolve disputes and impose criminal sanctions in the tribal council, a body that also possessed legislative and executive powers. Such intermingling of political responsibility and judicial responsibility is generally considered suboptimal because it often means that the individuals exercising judicial authority are subject to political pressures that may taint their judicial decisions.

Even when the judicial power resides in a formally separate institution—a judiciary—the relationship between the judiciary and other institutions of government may impair the ability of the judiciary to uphold the rule of law. Judges who rely on other government actors to secure their wages, to maintain their staffs and their facilities, and even to keep their jobs are understandably vulnerable to political pressures. Freeing the judiciary from these sources of dependence, specifically by institutional arrangements that make it difficult if not impossible for other government institutions to undermine the judiciary’s ability to function, advances judicial independence.

While it is easier to insulate the judiciary from public pressure, the separation of the judiciary from electoral influence poses more philosophical problems for democratic states, particularly when the judiciary exercises judicial review. The notion of a government entity that is not answerable to the public effectively exercising a veto over legislative acts runs counter to the idea of majority rule; for precisely that reason, some states opt to select judges through popular elections or allow the public to remove unpopular judges through recall elections.

Advocates of judicial independence argue, in response, that the judiciary provides a critical check on majoritarian government, protecting enduring political values and the interests of political minorities from fleeting political passions or minority tyranny. Proponents of judicial independence suggest appointing judges based on merit, for life tenure or for a fixed, nonrenewable term.

Even when institutional arrangements maximize judicial independence, the interplay between the judiciary and more political forces is apparent. For example,
of the U.S. federal judiciary are appointed by the president but must be confirmed by the Senate, and they enjoy life tenure. Still, historically, the federal courts have shown deference to political sentiment. The U.S. Supreme Court seemed to abandon principle to political pressure when it upheld the constitutionality of the Japanese internment during World War II (1939–1945) and when it shifted its position on economic liberty to allow adoption of the New Deal policies of Franklin D. Roosevelt (1882–1945). Even when the Supreme Court made the politically unpopular move of ordering the desegregation of public schools, the Court’s concern for public opinion was apparent; Chief Justice Earl Warren (1891–1974) carefully crafted his opinion in Brown v. Board of Education (1954) to ensure a unanimous Court, and the Court waited a year after declaring segregated schools unconstitutional before issuing the opinion ordering desegregation. In other words, even when the Supreme Court uses its independence, it often attempts to make concessions for public opinion.

VARIATION IN JUDICIAL SYSTEMS
While most judicial systems share a common purpose and certain common ideals, there is tremendous variation in the structure and function of judicial systems when viewed in comparative perspective. The rest of this article will focus on some of the key dimensions along which judicial systems vary.

Criminal Justice: Inquisitorial and Adversarial Systems
The judiciary often bears primary responsibility for the administration of criminal justice: adjudicating guilt and assessing sanctions for the violation of criminal laws. Criminal justice systems and, more specifically, the role of courts in those systems, may be adversarial or inquisitorial; these terms define endpoints on a continuum, with most judicial systems blending elements of both adversarial and inquisitorial procedures.

In a purely adversarial system, prosecutorial and adjudicating powers are completely separated. A prosecuting authority makes the decision to charge a citizen with a crime, gathers evidence of guilt, and argues on behalf of the state. The role of the judiciary is limited to receiving evidence from both the prosecutor and the accused, weighing that evidence, and adjudicating guilt. Thus the party adjudicating guilt and innocence hears both sides of the story, presented as cohesive wholes, in relatively quick succession.

In contrast, in a purely inquisitorial system, both prosecutorial and adjudicating authority are vested in a single institution. In an inquisitorial system, the same individual or institution will be responsible for charging a citizen with a crime and for determining whether the citizen is guilty. Judicial officials in inquisitorial systems gather evidence and directly question witnesses. The danger of an inquisitorial system is that during the course of investigation, the judicial authority will become committed to a particular theory or belief and that subsequent, countervailing evidence will not be accorded sufficient weight. In other words, inquisitorial systems create a real risk that prosecutorial zeal and momentum will cloud the ultimate determination of guilt.

Civil Justice: Common Law and Civil Law Systems
The role of the judiciary in the administration of civil justice—the resolution of disputes between private parties—varies considerably between common law countries and civil law countries. Common law countries are, generally, England and its former colonies, while the civil law tradition has its origins in France.

In the civil law tradition, the role of the judiciary is considerably more limited. Codified law is far more detailed and governs every aspect of social intercourse. The role of the judiciary is limited to interpreting those laws that have been enacted by the legislative branch of government.

Judicial Review: American and European Models
One dimension along which we can differentiate types of judicial systems is the manner in which they exercise judicial review. Judicial review is the process of evaluating new legislative enactments and executive policies to ensure that they are consistent with constitutional requirements. There are two principal models of judicial review: the European model and the American model.

The European model is characterized by a division between ordinary courts, which are typically hierarchical systems for addressing basic civil and criminal matters, and a constitutional court, which is a single court of limited jurisdiction devoted solely to the business of ruling on the constitutionality of legislative acts. France, Portugal, Germany, and Russia all have a constitutional court system. In these countries, when the legislature passes a new law, it may be challenged directly in the constitutional court. In some countries, such as France, the challenge
must come from a state actor. In others, such as Germany, even ordinary citizens may allege a constitutional violation.

The American system is considerably less efficient. The American judicial system is unified: there is a single, hierarchical federal court system—with trial courts, intermediate appellate courts, and a Supreme Court—that handles civil matters, criminal matters, and constitutional questions. Challenges to the constitutionality of legislative enactments must work their way through the complete hierarchy, a long and burdensome process. What’s more, the challenges must arise in the context of an actual case or controversy rather than as a simple allegation of unconstitutionality.

To illustrate, imagine a law forbidding the distribution of pamphlets critical of the government. In a country with a European system of constitutional courts, an individual who believes the law violates the country’s constitution would address this argument directly to the constitutional court; the constitutional court would rule up or down on the issue of constitutionality, and the dispute would be over. In an American-model country, however, an individual who believes the law is unconstitutional would have to create a case—likely by breaking the law, enduring arrest, and then challenging the constitutionality of the law during the course of his or her criminal trial. The challenge may need to be repeated in the trial court, one or more appellate courts, and finally the U.S. Supreme Court.

JUNG, CARL

1875–1961

Carl Gustav Jung was born in Kesswil, Switzerland, on July 26, 1875. Jung was a self-described lonely and isolated son of an emotionally troubled mother and a poor but extremely well-read country pastor. A gifted student, Jung originally wanted to be an archaeologist. Due to limited financial resources, Jung was forced to attend the University of Basel, which did not offer courses in archaeology, and he studied medicine with the intention of becoming a surgeon. Jung switched to psychiatry to pursue his interests in dreams, fantasies, the occult, theology, and archaeology. Upon graduation Jung received an appointment to the Burgholzli Mental Hospital in Zurich where, from 1900 to 1909, he studied the nature of schizophrenia and developed into a world authority on abnormal behavior.

Jung was an early supporter of the psychotherapist Sigmund Freud (1856–1939) because of their shared interest in the unconscious. When the International Psychoanalytic Association was formed in 1910, Jung became its first president at the request of Freud. However, growing theoretical differences between them, especially over the importance of libido (i.e., sexual energy) and the nature of the unconscious resulted in Jung’s resignation from the group only four years later. The two men never met or spoke to each other again.

From 1913 to 1917, while Jung was experiencing serious emotional difficulties in his life and even contemplating suicide, he engaged in an extensive self-analysis. The outcome of his self-analysis produced some of Jung’s most original theoretical concepts, which he continued to develop over the next sixty years as Jung established himself as one of the most noted psychological and eclectic thinkers of the twentieth century. For example, Jung was extremely well read in theology, anthropology, archaeology, psychology, ancient texts, the occult, mythology, and psychiatry. He studied psychological adjustment in selected groups of individuals around the world (e.g., Navajo Indians, native tribes in Africa); and participated in archaeological and anthropological expeditions in a variety of cultures (e.g., Egypt, Sudan, India), while incorporating his diverse knowledge and experience into his theory of personality and psychotherapeutic applications in an attempt to verify his ideas. Jung died on June 6, 1961, in Zurich at the age of 85. He was an active and productive researcher and writer his entire life, with a collection of works totaling twenty volumes.
FREUDIAN VERSUS JUNGIAN TRADITIONS

Although initially a strong supporter of Freud and his ideas, Jung's eventual disagreement with some of the cornerstones of Freud's theory resulted in the termination of their professional relationship and personal friendship. A principal source of disagreement was with Freud's concept of libido. Freud's conceptualized libido as primarily the source of sexual energy that served to create a state of emotional tension that the individual was driven to decrease, forming the basis of the two primary motivating sources of behavior—life instinct (i.e., creation of tension) and death instinct (i.e., the reduction of tension). In direct contrast, and much to Freud’s disagreement, Jung de-emphasized the importance of the libido as a source of sexual energy. Jung described libido as a more generalized life energy source that served to motivate the individual to seek a sense of personal balance within the psyche in a number of different ways, including socially, intellectually, emotionally, spiritually, and creatively.

This point of disagreement regarding the nature and role of libido helped to create the distinction between the Freudian and Jungian traditions in psychology. The Freudian tradition is characterized by the presence of intrapsychic conflict and the creation and reduction of psychic tension. The Jungian tradition, referred to as “analytical psychology,” is characterized by the seeking of intrapsychic harmony and the balanced expression of the separate aspects of the self.

THE STRUCTURE OF THE MIND AND ITS CONTENTS

Another significant source of disagreement between Freud and Jung was their contrasting views of the structure of the mind and the nature of unconsciousness. In comparison to Freud, Jung's view of the structural nature of personality reflected a redefined and expanded view of the mind, especially the unconscious mind, which Jung believed to be much deeper and wider in the scope of its content than Freud. The “conscious ego” is the center of conscious awareness of the self. The major functions of the conscious ego are to make individuals aware of their internal processes (e.g., thoughts or feelings of pain) and the external world (e.g., surrounding noises) at a level of awareness necessary for daily functioning.

Directly next to the conscious ego and below conscious awareness, Jung proposed the “personal unconscious” region of the mind. The contents of the personal unconscious include all thoughts, memories, and experiences that are momentarily not being thought about and/or repressed because they are too emotionally threatening. The most important elements in the personal unconscious are what Jung described as “complexes.” A complex is a collection of thoughts, feelings, attitudes, and memories that center around a particular concept. The more elements attached to the complex, the greater its influence on the individual. If the complex becomes too strong it can become pathological, serving to create a sense of imbalance in the individual's personality, such as a power complex associated with a dictatorial leader.

While the personal unconscious is unique to each individual, the collective unconscious was the region of the unconscious mind believed by Jung to be shared by all people. Jung conceptualized the collective unconscious as being “transpersonal” in nature. The transpersonal nature of the collective unconscious reflected Jung’s view that there is a region of the unconscious mind containing a collection of general wisdom that is shared by all people, has developed over time, and is passed from generation to generation across the ages. The principal function of this wisdom is to predispose individuals to respond to certain external situations in a given manner. For example, anytime a group of individuals gets together, there is a natural tendency or predisposition for them to establish a social order.

The most significant of these predispositions or images in the collective unconscious are referred to as “archetypes.” Archetypes are universal thoughts, symbols, or images having a large amount of emotion attached to them. Their special status comes from the importance they have gained across the many generations and the significant role they play in day-to-day living. Another concept Jung used to illustrate the universal connectedness of the collective unconscious was the principle of “synchronicity.” Jung used synchronicity to explain the occurrence of two meaningful events that do not appear to have any physical cause-and-effect sequence, such as dreaming of a distant relative’s death and then receiving news a week later that the relative had died on the same day you had the dream.

While there are a variety of archetypes, there are four archetypes that play a significant role in the establishment of a balanced personality: the persona; animus/anim; shadow; and self. The “persona” is an archetype that develops over time as a result of the tendency of people to adopt the social roles and norms that go along with living with other people. From the Latin word meaning “mask,” the persona reflects what might be defined as a person's public personality (e.g., being courteous in public). However, attaching too much emotion and importance to the persona can result in the individual losing contact with his or her true feelings and identity, which can then become dictated by others (e.g., an individual with a shallow and conforming personality). Jung believed that individuals were psychologically bisexual in nature in that each individual possesses characteristic features and ten-
dencies of the opposite sex that are represented by the archetypes of the animus and anima. The “animus” is the masculine aspect of females, such as being aggressive. The “anima” is the feminine aspect of males, such as being nurturing. The well-developed personality contains both masculine and feminine characteristics. The “shadow” represents the dark and primitive side of personality. Like the id developed by Freud, the shadow represents all of the instinctive and impulsive aspects of personality typically repressed in the unconscious regions of the mind and kept out of the public personality.

The “self,” the most significant archetype, is that element of the personality predisposing the individual to unite all other aspects of the personality. The development of the self as an archetype reflects the desire by people across generations to seek unity and harmony. Within the individual, the self is the motivating force seeking to achieve unity and harmony between all the private and public, masculine and feminine, and conscious and unconscious aspects of the individual. Failure on the part of the self to achieve this sense of unity and balance can result in the overdevelopment of one aspect of the personality at the expense of all others.

JUNG’S PERSONALITY TYPES
According to Jung there are two general types of personality attitudes by which individuals orient themselves toward their environment: extraversion and introversion. The “extraversion” attitude is an outward orientation in which psychic energy is invested in events and objects in the external environment (e.g., preference for group activities). The “introverted” attitude reflects an inward orientation in which psychic energy is invested in internal and personal experiences (e.g., preference for spending time alone). While Jung believed that both types of attitudes are present within each personality, he thought that in each person one attitude is expressed more at the conscious level than the other.

Besides the two basic attitudes of personality, Jung also proposed the existence of four functions of personality. Each function is characterized by a specific orientation for understanding the events and experiences in the environment.

- The “sensation function” involves relating to the world through the senses.
- The “thinking function” refers to the tendency to relate to the world through ideas and intellect.
- The “feeling function” concerns reacting to the world on the basis of the emotional quality of one’s experiences with it.
- The “intuition function” goes beyond all other conscious functions and relies on a deeper, more internal sense of understanding.

As with the two attitude types, Jung assumed that each personality possesses all four functions, but one is often expressed at a predominant, conscious level at the expense of the others.

The technique of personality assessment most closely identified with Jungian principles is the Myers-Briggs Type Indicator (MBTI). The MBTI is a self-report instrument using objective criteria (i.e., standardized response and scoring procedures) based on Jung’s type theory and designed to assess how variations in the expression of the two attitudes and four functions result in differences in the way individuals use perception and judgment as general orientations to their experiences when taking in information and making decisions. The utility of the MBTI can be seen in its use in a variety of areas, including literary criticism, career-counseling, organizational consulting, design of information technology, academic advising, and the health care industry.

THE NATURE OF MENTAL HEALTH AND ANALYTICAL PSYCHOTHERAPY
Mental health was represented by Jung as a balanced expression of the various archetypes. Jung proposed that well-adjusted individuals learn to incorporate private aspects of their personality into the persona and express them consciously in socially acceptable forms. The developmental concept of “individuation” is used to describe the process by which individuals become aware of the different aspects of their personality at both the conscious and unconscious level, and expend mental energy to develop and express them in a meaningful way. The development of “neuroses” is a result of the individual failing to achieve a sense of integration, resulting in the projection of the underrepresented aspects of the self (e.g., connectedness with others) on to others (e.g., blaming a spouse for not being affectionate), which serves to foster maladaptive interpersonal social relationships. The development of “psychosis” is a result of extreme and prolonged repression of underrepresented aspects of the self, resulting in the aspects exploding into the individual’s psyche in the form of drastic shifts away from the conscious, public persona (e.g., massive retreat into the unconscious mind and away from reality, as is with schizophrenia).

Based on Freud’s technique of psychoanalysis, Jung’s form of therapy is referred to as “analytical psychotherapy” and is characterized by a greater emphasis in the unconscious and the reestablishing of psychological balance within the individual. One method used to investigate the
unconscious was the word association test. The test, which Jung invented, was used principally to help identify the client’s problematic complexes. A problematic complex is characterized by the overinvestment of mental and emotional energy into one aspect of an individual’s personality (e.g., obsession with work) at the expense of other aspects of the individual’s personality (e.g., neglecting one’s family).

Going beyond the identification of problematic complexes, Jung analyzed dreams to explore the archetypes of clients using a technique referred to as the “method of amplification,” which he also developed. In this method the client not only reports what is going on in the dream but also expands on the details as if actually a part of the dream (e.g., describing how it feels to be free and very powerful, as represented by a sports car as a symbol of the self in the dream). To facilitate this process, Jung used the dream series method, which involved amplifying and analyzing a series of dreams for the repeated occurrence of particular archetype symbols (e.g., the self appearing as the sun or a tall building). He also used the method of active imagination in which the client is asked to imagine having an interaction with the significant archetypes identified during treatment (e.g., talking to a “mechanic/therapist” about making the “car/self” perform more effectively).

**Jung’s Relationships with Nazism**

In 1933 as Adolf Hitler came to power, the German Medical Society of Psychotherapy was reorganized based on National Socialistic principles in an attempt to remove its Jewish members. An International General Medical Society for Psychotherapy was organized in Germany and permitted individual membership, including Jewish members, and national societies, including the German Society. Jung was elected the International Society’s first president in 1933 and served until 1939. Jung also served as the chief editor of *Zentralblatt für Psychotherapie und ihre Grenzbiete*, a journal that eventually published an article promoting Hitler’s *Mein Kampf* as required reading for all psychoanalysts. Jung’s affiliation with this Nazi-dominated International Society led to accusations that Jung was a Nazi sympathizer. Jung maintained that his involvement with the International Society was an indirect attempt to make it possible for Jewish practitioners to maintain their professional involvement and help preserve psychoanalysis, which the Nazis viewed as a “Jewish science.” It should be noted that Jung resigned from the International Society for Psychotherapy toward the end of World War II (1939–1945), had public supporters who were Jewish, was blacklisted by the Nazis, and had his works suppressed in Germany and other occupied countries by the Nazis.

Despite Jung’s novel contributions to the study of personality and psychotherapy, the acceptance of Jung’s ideas has been limited by the vague definitions of his principal concepts (e.g., the collective unconscious, archetypes, synchronicity), which made his concepts difficult to test empirically by the traditional scientific methods. Given the difficulty in quantitative testing, Jung’s ideas have been more popular and influential in the more qualitative areas of scholarship, such as the humanities (e.g., literary criticism, mythology, and symbolism) and humanistic social sciences (e.g., anthropology and qualitative sociology) than the quantitative areas associated with postmodern experimental psychology and psychiatric medical research.

**Jurisprudence**

The term *jurisprudence* refers generally to the science or study of law and encompasses any effort to define, describe, or conceptualize the nature of the law. In practice, such efforts vary dramatically in scope and focus. Broadly speaking, jurisprudential efforts can be divided into two types: applied jurisprudence and the philosophy of law.

**Applied Jurisprudence**

Applied, or empirical, jurisprudence is the study of the nature and development of the law through its actual practice. In other words, the endeavor of applied jurisprudence is to examine judicial decisions in which rules of
law are applied to actual cases and conflicts, and from that application infer something about the nature of the law being applied. For example, one might look at a series of U.S. Supreme Court decisions that apply the establishment clause of the First Amendment to actual conflicts and, from those decisions, develop an understanding of what the establishment clause means and how it might be applied to other, hypothetical situations. This understanding and the judicial decisions giving rise to it would be known, collectively, as establishment clause jurisprudence.

Applied jurisprudence is particularly important in common law legal systems—primarily in England and its former colonies. Black’s Law Dictionary defines common law as “the body of law derived from judicial decisions, rather than from statutes or constitutions” (1999, p. 270). Common law systems are based on the idea that law derives primarily from custom or usage. In a common law system, the basis or grounds on which a court resolves a dispute comes from past decisions of the court; those past decisions are called precedents. Statutes and other codified laws may alter or supersede common law principles, but common law principles are used to interpret statutes, and traditional common law principles fill the interstices between codified laws.

In common law systems, legal norms develop incrementally over time, with judicial decisions announcing or explaining the law only when necessary to resolve the particular dispute before it. Anticipating how the law will be applied to a new factual scenario necessarily requires assimilating a large number of judicial decisions and analogizing to the new fact pattern. As a result, the endeavor of applied jurisprudence—looking at judicial decisions and, from them, discerning the nature of the law—is an integral part of the practice of law in common law countries.

PHILOSOPHY OF LAW
The term jurisprudence also refers to the philosophy of law, which is concerned not with the law of a particular state or country but with the nature of law more generally. The philosophy of law is concerned with the origin of law, the difference between law and other social norms, the difference between legal systems and other institutions, and the legitimacy of laws and legal systems. Some philosophical inquiries focus on what the law is, and these inquiries form the basis of analytic jurisprudence. Other philosophical inquiries focus on what the law should be, and these inquiries form the basis of normative jurisprudence.

Analytic jurisprudence addresses questions about what the law is: What do we mean by the term law? How do we come to understand the law? What differentiates laws from other norms and institutions? What is the relationship between the law and other concepts, such as power and morality?

Perhaps the most significant and fundamental issue in the context of analytic jurisprudence is the debate between natural law theorists and legal positivists. Put very simply, natural law theorists assert that law derives from a higher order, imposed by God or nature and adducible by reason; law exists independently of states and sovereigns, and law is inseparable from morality. A state may articulate a rule and use its coercive power to enforce that rule, but the rule is not genuinely law unless it conforms with some standard of what is right, moral, or just. Although philosophical writings dating back to Aristotle (384–322 BCE) reflect the theory of natural law, its most prominent champion in the twentieth and early twenty-first centuries is the Australian legal scholar John Finnis.

In contrast to natural law, legal positivism views law as a purely social construct and asserts that the law is what the sovereign declares it to be; the question of whether a law is good or right is distinct from the question of whether it is, in fact, a law. Some of the most notable proponents of legal positivism include the British jurist John Austin (1790–1859) and the British scholar H. L. A. Hart (1907–1992).

Legal interpretivism presents a conceptual alternative to both natural and positive theories of law. The interpretivist approach argues that law is not a fixed concept at all, but the result of legal practice. Rules articulated by the state must be interpreted, and their interpretation by legal practitioners is necessarily informed by those practitioners’ moral beliefs. Thus, law does not derive from morality but is shaped by it. The interpretivist approach is most often associated with the American legal scholar Ronald Dworkin.

Whereas analytic jurisprudence seeks to describe law and legal systems objectively and, in some circumstances, to address the relationship between law and morality, normative jurisprudence addresses the moral questions raised by legal problems: When should the rights of one person be compromised to protect the rights of another? Is a state justified in restricting an individual’s liberty to protect that individual by, for example, requiring the use of automobile seatbelts or prohibiting suicide? Why and how should violations of the law be punished?

Normative jurisprudential debates frequently invoke religious arguments and overlap with political philosophy. For example, one of the most enduring questions of normative jurisprudence is whether a state is ever justified in imposing capital punishment. Both the popular and scholarly dialogues on the issue frequently involve arguments based on religious teachings. Similarly, in the United States, the capital punishment debate is sometimes framed as a political question: As the ultimate restriction
on liberty, is capital punishment consistent with liberal democratic values?

JURORS, DEATH-QUALIFIED
In a process unique to criminal law in the United States, jurors in capital trials are subjected to a process known as “death qualification.” Since 1976 all criminal trials for which the death penalty is a possible sentence have been held in two different phases (producing what is known as a “bifurcated trial”): a guilt-determination phase, followed by a penalty phase if the defendant is found guilty of a capital crime. The rationale for death qualification is that justice in capital cases cannot be properly administered if jurors’ views about the death penalty are so strong that they prevent impartial decision making. So, during the voir dire jury-selection process, the prosecution and defense lawyers have an opportunity to “death-qualify” potential jurors by questioning them about their views regarding the death penalty.

Contemporary death qualification under the Supreme Court decision in Wainwright v. Witt (1984) eliminates potential jurors if they believe that their ability to function as a juror in a capital case would be impaired because of their views on the death penalty. This standard differs notably from that established previously by Witherspoon v. Illinois (1968), which excluded only those jurors who indicated such a strong opposition to the death penalty that they would not consider voting for a guilty verdict if there was even a possibility that a death sentence would be ordered.

Criticism of the death-qualification process has focused on two basic arguments: (1) that the process is unreliable, and (2) that the process creates systematic bias among the pool of eligible jurors such that they are predisposed toward guilty verdicts during the penalty phase. Research in this area generally has relied upon mock-juror and mock-jury studies in a social-psychological tradition, although sometimes researchers have been able to question jury-pool members and jurors who have served in actual capital cases.

A mock-juror study conducted by Ronald Dillehay and Marla Sandys (1996) suggested that the current Witt standard for excluding jurors in death penalty trials is unreliable, eliminating those who would ultimately be able to perform adequately as capital jurors and failing to identify some potential jurors known as “automatic death penalty” jurors who would always vote for the death penalty if a defendant had been convicted of murder. In addition, the death-qualification process itself may cause jurors to believe that the defendant is guilty and that a penalty of death is expected. Social science research also suggests that the death-qualification process may increase the likelihood of guilty verdicts during the first stage of bifurcated trials.

JURY SELECTION
The jury system is the cornerstone of the common law legal system, the legal system shared by England and most of its former colonies. The common law legal system is premised on the notion that legal norms develop through common practice rather than formal rules; juries—groups of people lacking formal legal training who are brought in to adjudicate disputes—provide the perspective of the community, a common rather than formal perspective. Because juries are essential to the common law legal tradition, their selection and composition affect the very heart of common law systems of justice. Jury selection systems vary from jurisdiction to jurisdiction, but the goal of all such systems is to convene juries that are representative of the broader community and that are unbiased.

Jury selection begins with the process of identifying those people who are eligible to serve. A list of potential jurors may be constructed from voter registration lists, drivers’ license and state identification lists, or other official rosters of citizens. The goal of a representative jury is best achieved with a comprehensive list of potential jurors;
Jury Selection

using voter registration lists as a source of potential jurors, for example, may result in a jury pool that underrep-resents certain demographic groups, such as the poor and young adults.

From the list of potential jurors, a jury pool is randomly selected. In smaller jurisdictions, where the need for a jury is rare, a jury pool may only be selected when the need arises. In most jurisdictions, however, jury pools are convened as a regular matter. From a single jury pool, multiple juries will be selected over the course of the pool’s service (which may range from a single day to several weeks to several months).

Individuals who receive a summons to appear for jury duty—to be a part of the jury pool—are generally asked to complete a short list of questions. Based on their answers, jurors may be disqualified—deemed ineligible to serve. Citizens may be disqualified for jury service because of a lack of language proficiency, mental or emotional disturbance, or a criminal record or pending criminal charges. Historically, in the United States, citizens were disqualified from jury service on the basis of their race or gender, but the U.S. Supreme Court has determined that such disqualifications are inconsistent with the equal protection clause of the Fourteenth Amendment to the Constitution.

Some potential jurors, while not disqualified, are nevertheless excused from jury service. In other words, while they may serve, they are not legally obligated to serve. Members of certain professions—doctors, teachers, lawyers, military personnel, and small business owners—as well as individuals whose physical condition would make jury service difficult, may be excused.

When a particular jury is needed for a particular case, names are randomly selected from the jury pool. These individuals—called venirepersons—are subjected to more detailed questioning by the attorneys and judge involved with the case. This questioning process is known as voir dire. The purpose of voir dire is to identify particular biases a juror might have that would affect his or her ability to be objective in resolving the case: knowledge of the parties to the case, witnesses, or attorneys; exposure to prejudicial media coverage about the case; past experiences that might color the juror’s judgment; or even biases against certain groups of people.

On the basis of the venirepersons’ answers to questions during voir dire, attorneys may challenge their ability to serve on the case. Specifically, attorneys may use two types of challenges: challenges for cause and peremptory challenges. In a challenge for cause, the attorney requests that the judge strike the potential juror because of some obvious bias. For example, in cases involving the death penalty in the United States, the prosecuting authority is entitled to a jury of individuals who are not opposed to capital punishment; such a jury is said to be death-qualified. If, during the course of voir dire, a venireperson expressed opposition to the death penalty, the prosecuting attorney could challenge that venireperson for cause.

Attorneys can use peremptory challenges to strike jurors who are not clearly biased. Peremptory challenges give attorneys the opportunity to strike jurors whose answers do not necessarily reflect bias but whose demeanor or background raise concerns for the attorney. Attorneys use questions about the types of television shows jurors watch, the books they read, their hobbies, and even the bumper stickers on their cars to develop profiles of potential jurors and to expose unspoken biases. While there is no limit to the number of potential jurors who may be struck for cause, each party to a case has a fixed number of peremptory challenges and, once they are exhausted, may not exercise any more.

Peremptory challenges are controversial. In England, peremptory challenges are not allowed. In the United States, peremptory challenges are allowed, but they cannot be used to eliminate jurors on the basis of race or gender, and there is considerable variation in how the process is implemented. Specifically, some jurisdictions use a sequential system, while others use what is called a struck system.

In a sequential system, the number of venirepersons empanelled equals the number of individuals needed for the jury, so that when a party uses a peremptory challenge to strike a venireperson, that party has no idea what the replacement venireperson will be like. A party may use its last peremptory challenge to strike a venireperson only to find that the replacement venireperson is even less desirable. In a struck system, however, the number of venirepersons chosen equals the number of jurors required plus the total number of peremptory challenges the parties may exercise. Thus, a party may use its peremptory challenges to eliminate the least desirable of a known set of potential jurors.

Once both parties have passed the jury panel for cause—concluded that everyone who remains is capable of serving impartially—and have exercised all of the peremptory challenges they choose to use, the remaining venirepersons are issued an oath of service and become the jury. While no jury is perfectly representative and some personal bias is unavoidable, the iterative process of random selection and careful screening increase the likelihood of a jury that reflects community values and common sense in legal decision making.

JUST WAR

“Just war” principles seek to transform war and peace into moral questions, to move international relations beyond the “realist” conception classically expressed in The Peloponnesian War by the fifth-century BCE Greek historian Thucydides. A realist conceives of wars as a normal if undesirable fact of international relations, a matter of irreconcilable national interests or policies in which the “royal prerogative,” the authority to decide for war or for peace, is an inherent sovereign power of governments. The realist is dubious about the contention that, in a world order still characterized by anarchy, war can be conceived at its root as a moral matter, although moral considerations can certainly be compelling in one way or another. To a realist, wars have occurred in history because, as the French philosopher Jean-Jacques Rousseau (1712–1778) said, there is nothing adequate to stop them. To a just war advocate, on the other hand, realism is far from irrelevant, but it is only the beginning of civilizing, that is, justifying and limiting humankind’s most damaging activity.

But just war principles are not at all the same as pacifism. Just war theorists argue that all war is in some sense evil, yet some wars are justified. A universal presumption against war, let alone a national policy of nonviolence, would be not only self-destructive but immoral because sometimes war is both necessary and right, particularly wars of self-defense against aggression.

CRITERIA FOR A “JUST WAR”

A just war is a right use of force founded in the moral responsibility of a government for the political community as a whole. In just war thinking, the “Westphalian system” launched in 1648 was based on a great mistake. This system refers to the modern international order consisting of sovereign nation-states, established by the European Treaty of Westphalia in 1648. Sovereignty was defined in purely procedural terms, implying that whoever successfully controls a territory should be accepted internationally as sovereign in it. The result was that, until quite recently, dictators used the legal principle of national sovereignty as a shield to protect themselves while tyrannizing their own people. Just war principles attempt to inject the concept of sovereignty with substantive moral meaning.

The just war idea has roots in ancient Israel and was first conceptualized in Catholic tradition by Augustine (354–430 CE), the bishop of Hippo, in The City of God. The Italian natural law philosopher Thomas Aquinas (1225–1274) gave the classic statement of just war principles in Summa Theologica. According to Thomas Aquinas, a just war is defined by two sets of criteria: whether the cause is just (jus ad bellum) and whether the methods of combat are just (jus in bello). Just war is thus an issue of both means and ends: A just war may be fought unjustly and vice versa. While the principles are fairly clear (although not entirely without ambiguity), controversy is inevitable in judging any particular case, a theme particularly well developed in the work of the influential American just war theorist Michael Walzer (2000).

Walzer argued that a just cause for war exists if five criteria are met. (1) The intention must be right, meaning a war must be waged either in self-defense against aggression or it must be an international intervention to aid another people victimized by egregious aggression. Since World War I (1914–1918), certain states (especially the United States) and international organizations (the United Nations, the North Atlantic Treaty Organization [NATO], and the European Union) have invoked a right to intervention on moral and humanitarian, as well as realist, terms. Since the 1990s, the international community, in the United Nations and outside it, has begun to codify not only a right to intervene but also a duty to do so—a “responsibility to protect” peoples in danger, a duty to reverse grave violations of human rights. (2) The decision to go to war must be made by a duly constituted sovereign, that is, a legitimate authority. (3) War must be a last resort, the ultima ratio, undertaken only after all diplomatic means have failed. (4) There must be a reasonable probability of success, the reason being to avoid futile damage. (5) The good to be achieved must clearly outweigh the harm to be done, the intrinsic evil aspect of even a just war.

In terms of the means of combat, a war is considered just if it meets two conditions. The principle of “discrimination” must be respected, that is, distinguishing insofar as possible between combatants and civilians, and strictly limiting the “double effect” or “collateral damage” of killing innocents while fighting. In addition, the principle of “proportionality” must be respected, meaning that

**BIBLIOGRAPHY**

*Wendy L. Watson*
damage inflicted must bear some reasonable relationship to the original aggression.

In retrospect, the catastrophic world wars and genocides of the twentieth century paradoxically emphasized both the continued relevance of realist international-relations thinking and the desirability of moving toward just war principles. For example, the Geneva Conventions on protection of prisoners of war and the prohibition of torture may be considered just war treaties. The Holocaust, the atomic bombings of the Japanese cities of Hiroshima and Nagasaki, and the firebombing of German and Japanese cities during World War II (1939–1945) have led to a widespread conclusion that genocide or the use of weapons of mass destruction can never be justified.

The American-led Gulf War of 1991 to reverse Saddam Hussein’s invasion and annexation of Kuwait, the European-American intervention in the Balkan wars of the 1990s, and the post–September 11, 2001, war in Afghanistan all were fought as just wars, that is, moral campaigns larger than the evident interest of the international community in reestablishing peace and security. There may be serious argument about whether or not any particular war is a just war (for example the American-led invasion of Iraq in 2003 to overthrow Saddam Hussein’s regime). But at the beginning of the twenty-first century it is evident that moral arguments about goals and methods of war are increasingly relevant in the real world of international relations, as opposed to realist Westphalian-type declarations of national interest or policy. This is fundamental moral progress, even as it is obvious that prudence remains the statesperson’s necessary virtue.

“JUST WAR” AND TERRORISM

The new age of global-scale terrorist attacks has obvious relevance for just war thinking. On the other hand, evaluating the justice of terrorist campaigns, although it may seem simple, is no easy matter. Judgments are not intuitive and the results are a matter of sharp dispute in world politics in the early twenty-first century. While it is insufficient simply to say that “one man’s terrorist is another man’s freedom fighter,” distinctions can and must be made in the real world or else it is too easy to end up in a situation in which might, or the most effective propaganda, makes right. Gradually, as with other aspects of international law, such as outlawing torture and genocide, increasing consensus about terrorism across different kinds of states, cultures, religions, and world regions may emerge. One example of international agreement on a definition of terrorism is found in the 2004 United Nations report, “A More Secure World.”

Terrorist acts are a tactical means of waging war. In just war terms, terrorism is illegitimate and unjust in itself, no matter how much sympathy this form of fighting may inspire in a civilian population. However, it is important to remember that terrorist groups are unaffected by this, since they reject the customary international laws of war as such, invoking their own, usually religious conception of just war ends and means. Terrorist groups, especially the new phenomenon of global terrorist networks, willfully defy the principle of discrimination by intentionally targeting civilians on a wide scale in an attempt to instill destabilizing fear in governments and populations. There is a sharp difference, at least in principle, between the intentional killing of innocents and military action that kills or wounds civilians in spite of genuine attempts to limit such damage, generally called collateral damage. In just war theory, intentions are fundamental, and the fallacy of moral equivalence—that is, civilians killed are civilians killed, no matter what the circumstance—must be avoided.

On the other hand, the concept of collateral damage can be dangerous because it can become overly expansive. For example, in spite of rigorous attempts to limit the killing of civilians in certain ways, a given state’s overall military campaign against terrorism may involve collateral damage on such a scale, with a more or less hidden intent to terrorize a population and turn it against erstwhile popular terrorist groups (themselves fighting with unjust means), that the military campaign itself becomes state-sponsored terrorism. In other words, terrorism may be a weapon of duly constituted, sovereign authority.

Furthermore, a terrorist group may in fact be fighting for a just cause—for example, it may be a military wing of a national liberation movement seeking national sovereignty and independence against a colonialist foreign power, or one or both sides in a civil war. Success of a terrorist campaign in such a case will not be military victory; rather, its goal will be to demoralize the adversary’s military or political leadership or its home population to the extent that a negotiated compromise or even total withdrawal may result. In such a case, a terrorist campaign that historically was only one aspect of a successful struggle for national independence may be remembered differently than it would have been had the struggle been lost.

In any case, however, terrorist acts on any side remain in and of themselves unjust and illegitimate. It is wrong to take any innocent person’s life, whether or not it can be claimed that a just end is being served. It is a fallacy to contend flatly that “just war trumps unjust means.” At the same time, just war judgments must somehow recognize a situation in which a rebellion’s use of only just means will leave a population more or less defenseless against an even more unjust power—whether the latter is its own government or an outside power. In such a case, agreement might be reachable by saying that, as with war itself, all
terrorsim is evil but it is always justifiable to choose the lesser evil.

Altogether, just war principles are not—far from it—a single unified doctrine that will easily unite the world politically or could be easily codified in international law. They represent moral guidelines, extending long-established, basically pragmatic, realist laws of war. They constitute a broad set of standards continuing a secular struggle to justify war in human terms and to limit its damage, against which individual cases can be argued and measured. Again, just war thinking does not envisage the abolition of war, because sometimes war is not only necessary but right.

Perhaps the appropriate conclusion at this point is to say that just war thinking is simultaneously a beginning and a hope, above all if, as increasing numbers of thoughtful people agree, war is a cultural phenomenon rather than human fate. Cultural practices may evolve in response to circumstances. In any case, realism and prudence will remain, at least for some time, the necessary foundations of international policy in a world order still characterized by anarchy.

JUSTICE
Justice is a moral quality of individuals and of institutions, whereby they give equality of respect to persons and strive to preserve the rights of all. Along with wisdom, courage, and moderation, justice was considered by ancient Greek as well as medieval Christian and Islamic thinkers to be a cardinal virtue. In the Republic, Plato (c. 427–347 BCE) portrays justice as the right ordering of the parts of the individual soul and the groups of persons in the city. Aristotle (384–322 BCE) devoted a central chapter of the Nicomachean Ethics to the virtue of justice. He distinguished between general justice, which is the complete exercise of all the virtues in one's treatment of other persons, and special justice, which is both the fair distribution of honors, wealth, and other goods, and fairness in the exchange of goods. Later tradition followed Aristotle by distinguishing between distributive justice (justice in the allotment of commonly held goods) and commutative justice (justice in exchange and in rectification of injuries). Distributive justice is governed, for Aristotle, by equality, but not by identical treatment for all. If “the people involved are not equal, they will not [justly] receive equal shares” (Aristotle 1985, p. 123). Whether one is wealthy, of good birth, or virtuous are among the factors that are believed by different people to affect one's just share of common goods, according to Aristotle.

Medieval philosophers followed the Greeks in defining justice as part of the natural law, those laws governing human actions that are founded in reason, in the human need to live in societies, and ultimately in a divine ordering of the universe.

MODERN ACCOUNTS OF JUSTICE
Modern political philosophy, although still sometimes using the language of natural law theories, transposed the discussion of justice into a social contract framework of thought. The English philosopher Thomas Hobbes (1588–1679) argued in Leviathan (1651) that prior to the establishment of a government, people lived in a state of nature, a state of war in which their lives and property were utterly insecure. In the state of nature, justice and injustice did not exist: “Therefore before the names of just, and unjust can have place, there must be some coercive power, to compel men equally to the performance of their covenants, by the terror of some punishment” (Hobbes [1651] 1962, p. 113). Justice, for Hobbes, has its ground in self-preservation and self-interest. John Locke (1632–1704) argued in the Second Treatise of Government (1690) that even in the state of nature people have a natural right to life, liberty, and property. The rulers, once the commonwealth is established, are obligated, according to Locke, to preserve these natural rights of individuals. Thus justice, for Locke, predates the establishment of the government and places some constraints upon the actions of those in power.

JUSTICE AND UTILITARIANISM
Utilitarian philosophy, resting as it does on the principle that the rightness of actions and of social institutions depends on the degree to which they promote human happiness, has often been charged with disregarding justice. Because the happiness of the greatest number could, at least in theory, result from unjustly depriving a minority of their rights or even of their lives, utilitarianism is often accused of failing to account for intuitive and traditional judgments about justice toward individuals. In defense of utilitarianism, John Stuart Mill (1806–1873) argued in Utilitarianism (1863) that the claims of justice, including individual rights to life, liberty, and property, as
well as the right of individuals to be dealt with truthfully and impartially, are fully compatible with utilitarianism. Because there can be no security for anyone unless each is treated justly, Mill argued, justice is the foundation of any society that seeks to promote the general happiness. Mill acknowledged widespread disagreement over such issues as whether those with greater talents or skills should be rewarded better than those without and whether taxes should be assessed based on the ability to pay or as an equal share.

A number of questions emerge from the foregoing sketch of historical views of justice: Should justice be considered a social convention or does it have a basis in natural or divine law? To what extent does justice, which demands that everyone be treated in some sense equally, admit that different treatment is appropriate in different cases? What are the differences (e.g., of individual merit or of need) that appropriately lead to differences in treatment?

### RAWLIS’S THEORY OF JUSTICE

The American philosopher John Rawls (1921–2002) was the twentieth century’s most influential thinker concerning these questions. In A Theory of Justice (1971), Rawls argued that justice is at its basis a matter of fairness. Justice, for Rawls, is “the first virtue of social institutions, as truth is of systems of thought” (Rawls [1971] 1999, p. 3). Rawls’s theory advocates a form of procedural justice, meaning that justice results from following a fair procedure, where there is no separate measure of what a just outcome would be. In the tradition of social contract theory, Rawls describes a hypothetical “original position” in which free and equal parties agree to the principles of justice by which society will be governed. To ensure fairness, the choice is made behind a “veil of ignorance” in which each of the contracting parties is denied knowledge of certain facts about themselves. None of them knows “his place in society, his class position or social status, nor does anyone know his fortune in the distribution of natural assets and abilities, his intelligence, strength, and the like” (p. 11). The parties are ignorant of their gender, and they do not know to what generation they belong. They know that when the veil is lifted they will have some conception of the good, that their notions of the good life will require some measure of resources to carry them out, and that those resources will be somewhat scarce.

Once the agents of the original position have been presented with a variety of available conceptions of justice, Rawls argues that they would adopt what he calls the two principles of justice. “First: each person is to have an equal right to the most extensive scheme of equal basic liberties compatible with a similar scheme of liberties for others. Second: social and economic inequalities are to be arranged so that they are both (a) reasonably expected to be to everyone’s advantage, and (b) attached to positions and offices open to all” (Rawls [1971] 1999, p. 53). Rawls gives priority to the first of these principles, such that basic liberties “can be restricted only for the sake of liberty” (p. 266). He refines the second principle (termed “the difference principle”) to say that inequalities are to be “to the greatest benefit of the least advantaged” (p. 266). As a result of adopting these principles of justice, Rawls defends a liberal constitutional democracy in which the government protects basic liberties and oversees the just distribution of resources. The principles of justice led Rawls, in his 2001 book Justice as Fairness: A Restatement, to criticize welfare and laissez-faire capitalism, as well as state socialism having a “command economy,” in favor of “property-owning democracy” and “liberal socialism” (Rawls 2001, p. 138).

In his 1993 book Political Liberalism, Rawls argues that the principles of justice are subject to an overlapping consensus, that is, that they are acceptable from the perspective of many different philosophical or religious systems of thought. In this way, Rawls advances the discussion of the principles of justice without requiring a decision on whether justice is ultimately a matter of social convention or of natural or divine law.

Though not a strict egalitarian (for he allows inequalities as long as they are to the advantage of the least well-off), Rawls views as unjust any distribution of goods that serves only to better the conditions of those possessing greater natural or social advantages than others. It is important to note that, for Rawls, individual endowments such as talent, wealth, and social standing are arbitrary gifts of fortune rather than individual possessions or entitlements. The “difference principle” ensures that those who possess such advantages will not be able to translate them into a greater share of society’s goods at the expense of those who are less advantaged. Thus, on the question of whether merit, need, or some other criterion should become the basis for the distribution of social goods, Rawls asks that we remember that what appears to be an individual’s “merit” is generally the result of luck rather than desert.

### OBJECTIONS TO RAWLIS’S THEORY

Rawls’s work has been widely praised and criticized. Communitarian critics, such as Michael Sandel, have objected that the parties in the original position are artificially deprived of the knowledge that membership in a particular community is essential to their identities, leading to an overly individualistic account of justice. Libertarians, including Robert Nozick (1938–2002), viewed Rawls’s principles as leading to infringements of individual liberty because of Rawls’s willingness to redis-
tribute social goods that were initially obtained through what libertarians view as legitimate means (e.g., not obtained through deceit or coercion). Advocates of Catholic social teaching, along with other religiously oriented thinkers, have objected that Rawls's thought relegates religious belief to the private sphere, thereby denying the important role of religious faith in the promotion of social justice. The feminist political thinker Susan Moller Okin (1946–2004) argued that Rawls overlooked the need for justice within families. Advocates of capability ethics, including Amartya Sen and Martha Nussbaum, criticized Rawls for stressing the equal distribution of goods without noting the differing degrees to which society enhances or undermines individuals’ capacities to make use of those goods. (Nussbaum has, in her own work, extended the discussion of justice to include questions of justice toward the disabled, toward nonhuman animals, and across international boundaries.) Despite these and other objections, Rawls’s theory, with its powerful defense of individual rights and its attention to the claims of the disadvantaged, continues to exert a commanding influence on contemporary ethical and political thought.

JUSTICE, DISTRIBUTIVE

Distributive justice refers to a process whereby a society allocates certain rewards and resources to persons based on a moral belief or set of moral beliefs. Once a typical feature of envisioned social utopias, ranging from a late medieval scheme of Thomas More (1478–1535) to the more modern experiments of thinker-activists like Robert Dale Owen (1801–1877), allocation became linked to modern theories of justice with the rise of bourgeois democracies. Jeremy Bentham’s (1748–1832) liberal utilitarian creed of the greatest good for the greatest number was contrasted in the nineteenth century with oppositional calls by radical thinkers from anarchist, socialist, and communist movements for a collectivist justice based on some form of economic leveling or allocation to each according to his or her needs.

The call for distributive justice found its expression in the transformation of Western bourgeois democracies into social democracies, along with the development of a postrevolutionary form of state socialism in the Soviet Union. The first consisted of state-centered provision of various forms of universal insurance, as well as of a full range of social and human services, and was financed typically by more progressive income and inheritance taxes. Greater equity, but not broad-based economic equality, resulted. Scandinavian countries, notably Sweden, had the greatest success in reducing income and wealth differences. The Soviet Union achieved much greater equity, though the creation of a nomenclature consisting of party officials and state bureaucrats did great damage toward attempts to achieve absolute economic equality.

Since the 1970s with the decline of Communist regimes and a general retreat from socialist/reformist thinking, there has been a return of more liberal calls for greater economic and social equity. They possess a twofold and somewhat contradictory character. First, they are decidedly more individualist and libertarian in their concerns. Modern philosophers in the Anglo-American tradition, such as John Rawls (1921–2002), stress the need to provide individuals with adequate resources for fulfilling lives—equality of opportunity, in a phrase. The leveling process, contrary to utilitarian and generally socialist aims, is clearly curtailed in this tradition by the desire to protect individual liberty and the freedom of choice in the economic transactions of civil society. Ronald Dworkin argues for an equality of outcomes, insofar, however, as persons are prudent and responsibly choose forms of insurance that could be offered by a state to compensate persons from potential or real harms.

Simultaneously, distributive justice has acquired a distinctly collective sociological character. The modern study of invidious distinctions ranging from class and caste to status, and the differences among persons thereby, have created a more radical theory of justice based upon the elimination of economic and social inequalities arising from membership in disadvantaged classes based upon income, wealth, race, gender, sexuality, and disability.
Empirical social science has provided extensive documentation that has been used by judiciaries, legislators, public administrators, and policy formulators to construct a variety of remedies, ranging once more from providing equality of opportunity to the more demanding requirement of equality of outcomes. The latter often requires limiting the freedom of others more privileged in some sense and of transferring resources to members of disadvantaged classes in amounts equal to or greater than amounts available to those not suffering from the disadvantage(s) under review.

More recently, economist and philosopher Amartya Sen has sought to join concerns for the well-being of individuals with the disadvantages they acquire as members of a discriminated class. Every individual, Sen argues, is an assemblage of specific capabilities. To provide equality of opportunity, interventions need to provide resources that strengthen an individual’s capabilities to function in a manner she finds conducive to her well-being. Her freedom of choice is preserved, along with her desire to live her particular life. To get resources to individuals with discernible capability deficits, Sen argues strongly that resources must be targeted to specific kinds of persons rather than simply added to a society’s macroeconomic mix. Hence, the individuality of deficits is matched with ameliorative social programs based upon the realization that deficits can be identical, person to person. Gender inequality, for instance, commonly affects certain women who could be grouped into a class, while this same class could differ from other women with another provenance.

This shift in the concept of distributive justice from universal entitlement to individual capabilities in the 1990s has had an enormous influence on social policy. International assistance to poor countries by the World Bank, rich countries, and nongovernmental organizations has been redirected from capital-intensive infrastructure projects to expenditures on public health and basic education, as well as gender-related remedies founded on the widespread recognition that women’s capabilities are sorely damaged by discrimination worldwide. In rich countries, the focus on individual capability deficits has led to a restructuring of income support programs that seek to hold individuals more responsible for their own development.

The calls for more equitable forms of distributive justice have stimulated a variety of opposition responses. The first might be termed a naturalist response. Persons are composed of innate differences in a variety of aptitudes that cannot be overcome by programs of distributive justice. Even if persons are compensated in ways that provide each with economic equality, natural differences will express themselves in the original cohort or in their progeny to re-create natural differences in aptitude once more. Charles Murray and Richard Herrnstein (1930–1994) argue that differences in intelligence lead to the formation of an elite based upon their superior abilities, and subaltern status for those less fortunate. A second, less genetically based version posits that subaltern groups form destructive ways of life that greatly diminish their chances for well-being. This position is typically referred to as the culture-of-poverty argument.

A second response bears a long and distinguished genealogy, and viewed from this end of the telescope is a profoundly sociological account of the origins and development of society. There are several sources. Thomas Hobbes (1588–1679) argues that the very equality between persons in the original state of society creates a drive for aggrandizement on a person’s part, if only to protect one from the envy and finally aggression of another. A state thus becomes necessary to protect each from all. John Locke (1632–1704) held a more congenial view of humankind, believing that persons were self-possessed and cognizant of their own needs and wants. The products of their toil, Locke argued, were theirs. The acquisition of property, however, provided them with a place for amicable exchange but also of legal defense against others in an organized society. Money creates a fetter in this otherwise peaceable kingdom, requiring that a civil government adjudicate fairly the disputes that arise between persons, especially as they become more unequal.

Both the more punitive motivations of Hobbes and the more genial motivations of Locke contribute to a modern, minimalist view of the state whose justice consists of ensuring fairness in the exchanges of individuals. Often called the night watchman state theory, its principal exponent in modern discourse is Robert Nozick (1938–2002). The job of the state, on Nozick’s view, is to repel national invaders and enforce contracts. As humans are their own property and not that of others, they are entitled to whatever property they acquire through their efforts—in fact, as much as they can acquire so long as they do not destroy the property of others or that of the commons. The state guarantees free markets in property, capital, and labor. Justice is no longer connected with distribution, but instead associated with equitable rules applied in the marketplaces of society.

This broad view has been used to support free-market-based economic and social policy. In the social sciences, it underlies the increased resort to so-called rational choice theory, whereby individuals are taken a priori to be rational, and create society via interactions on their own behalf. However, from this same premise, this notion that the self-interested person is a rational person can be severed from a purely means-ends rationality and applied to assumptions about the strength of greed, network, and group ties in orienting action.
This position also affected the nature of the social scientific investigation of inequality. Considering the broad endorsement of a kind of first-order naturalness to unequal social existence, investigators from the functionalist tradition in the postwar period produced descriptive paradigms of economic and social inequality in modern societies, and between rich and poor societies, that abjured comment on the moral and political dimensions of their studies. Their fundamental premise was that societal development necessitated an increasing division of labor, and inequality was its inevitable—and valuable—result.

A strong critical and highly politicized movement developed across the social sciences to combat what was seen as this received view. As a consequence, normative theorizing about inequality and the value of forms of distributive justice now constitute themselves as the normal conditions of discourse.

JUSTICE, SOCIAL

There are two important types of justice. Procedural justice, a primary goal of Western law, focuses upon using and implementing decisions according to fair processes. Substantive justice, on the other hand, reflects the content of the result of procedural justice and often is concerned with deeper issues of equity. Procedural justice can be viewed in terms of whether the process of punishment appears objectively fair to outside observers, while substantive justice can be interpreted in terms of whether a punishment subjectively is perceived as fair by the participants inside the process. Theories on justice and equity, and the implementation of these ideals, are usually found in philosophical literature. Justice as a concept typically is presented as universal and transcendent rather than as grounded in a social reality that has a particular historical and comparative context. Most of the dominant theories focus on the normative goal of what justice should be rather than studying how justice is defined by societies in specific places and at particular times. These concepts increasingly are used and imposed via hegemony (Gramsci 1971); that is, they are often exported through processes of cultural imperialism (Fanon 1967).

ENTITLEMENT AND UTILITARIAN VIEWS OF JUSTICE

The entitlement or libertarian view of the American philosopher Robert Nozick (1938–2002), the utilitarianism of John Stuart Mill (1806–1873), John Locke’s (1632–1704) concept of consensual constitutional government, and the social contract of Immanuel Kant (1724–1804) via the American philosopher John Rawls (1921–2002) represent some of the more popular Western
theories of justice. Justice from these perspectives often serves as a source of legitimacy for the development and use of law. Justice from an entitlement perspective emphasizes the importance of private property and individual freedom in juxtaposition to the increasingly controlling role of the state. Entitlement stresses the importance of liberty and efficient economic relations—whereby liberty is posited as more crucial than equality. As a transfer of property, however, such a system of social relations has not been realized in practice. Specifically, its assumptions about fairness in acquisition and transfer not only have proved unworkable, they are a central part of the allegiance to entitlement for the privileged and typically reproduce or increase inequity in class and community relations. When put into action, entitlement theory has placed efficiency before equity, and greater inequality has ensued.

Justice from a utilitarian point of view following Mills’s demands that society provide the greatest utility or happiness to the greatest number, the majority. A dominant part of this theory requires that people treat each other equally, yet equity can be sacrificed for the greatest utility or happiness. However, as Rawls argues, natural endowments should not determine material outcomes, although this theory of merit, too, can be revised in light of what most benefits the common good. More problematic is how the majority often has been defined—for example, Aristotle’s (384–322 BCE) exclusion of slaves in ancient Greece, and the exclusion of indigenous peoples in many modern nation-states. In the Western tradition, the “majority” typically is defined as those who support, implicitly or explicitly, the Western liberal project and the narrow meaning of rational “man” and are uncritical of technological development. Following the current standards of most international organizations, however, the majority of the population in the world consists of “minorities.”

Rawls’s social-contract metaphor presents the idea of a veil of ignorance to correct such inequities. Behind this veil, individuals make decisions about fair and equitable resource allocations. The role of conventional policymaking in implementing the contract reveals, however, consistent allegiances to uncritical plans of development promoting, once again, efficiency over equality. Policymakers and planners often do not serve the interests of justice because they or their political authorities serve their own interests at the expense of others. Rawls’s justice principle—that development for some is justified only if it benefits all—becomes circumvented.

The problems mentioned above can be addressed by deriving principles of justice from a particular historical and comparative context. Justice can be examined within social relations and material conditions that are specific and concrete. In this context, justice can become an important tool for analyzing change, “development,” and the use of law. Legal equality, for example, is an abstract ideal that often has been employed as a metaphor for justice. From the Western perspective on liberalism, in the United States in the eighteenth century, for example, the individual was defined as autonomous, the fundamental unit of society. Rather than viewed as subjects, individuals were defined as citizens who were born equal and free. This definition excluded the majority. Under the declaration that all “men” are created equal, women, poor men, and slaves were ignored. Legal equality for women, poor men, and slaves did not become a fact until the twentieth century. Legal equality, therefore, far from being a reality, can be viewed as a metaphor that emerges from specific, historical conditions.

As the twentieth century progressed, the modern nation-state legitimated its control and expanded its jurisdiction by deconstructing indigenous solidarity, experiential education, and family and community welfare as it constructed national citizenship, formal education, and limited forms of government welfare for individuals. Concepts of nation-state and citizen were presented as major sources of solidarity and identity, emphasizing an abstract concept of nationalism. Formal education was proclaimed as superior to experiential learning. The nation-state centralized welfare amid claims of its progressive care, yet modern forms of state welfare usually have created varying levels of stigma for recipients.

**THE NEED FOR COMPARATIVE AND HISTORICAL ANALYSIS OF JUSTICE**

Justice, then, is a useful concept when one examines how it is constructed in different social and political settings and explores how it is used as a source of legitimation for the development and use of rules such as law (Lauderdale 1997). The study of justice should include an analysis of the fair distribution of benefits and burdens, including rights, obligations, deserts, and needs. This manner of studying justice also differentiates between short- and long-term impacts of change, and may identify well-intentioned suggestions for change that may result in unfortunate consequences. The comparative and historical analysis of theories and practices of justice is a relevant alternative to most perspectives on what justice should be. A commitment to addressing the injustices committed in the past by making the lives of people who have suffered those injustices more secure, peaceful, and prosperous may benefit those people who have (directly or indirectly) benefited from historical injustices (Thompson 2002).

A comparative and historical analysis of justice also considers the crucial role of noneconomic factors, such as
religious beliefs and ideology, which people sometimes privilege over the goals of Western development. Liberation theology, for example, appeared as a religious social movement in reaction to the binding ties between the elites and the Catholic Church, which exacerbated obvious inequities, especially those of land use and ownership (Gutiérrez 1988). The theology began not with theory but with the realities of injustice experienced by the peasants and indigenous people of Latin America. It calls for individuals, communities, and corporate entities to be involved in extricating themselves from serving the interests of the elites of society and instead to work on behalf of the marginal with the goal of establishing solidarity and equity. Working with the oppressed is presented as a pragmatic prescription to fight poverty and oppression and to liberate people here and now. From such a perspective, justice is revealed as a structural phenomenon, and the dynamics of the world market system, promoted in tandem with liberal democratic principles, are shown to be unjust.

Such approaches to justice stress the development of peoples and not economies, emphasizing the conditions under which economic and political dependency works against community determination and autonomy. The perspective, then, is about whether certain kinds of growth can really solve the problems at hand. The dominance of capital or economic interests as the developing principle is seen as contradicting the ethical principle that workers and labor must be given priority in development of an economy based upon justice. Here, there is a principle that there must be an ethics of means as well as ends. The scholasticism found in many ethnocentric theories of justice based on Western philosophy can benefit from analyses of where perceptions of justice emerge.

Theories of justice based solely on abstract and universalistic criteria have been unable to respond to people throughout the world who are experiencing the presence of injustice in the form of poverty, landlessness, dispossession, political and religious oppression, and genocide. Philosophical formulas of justice are inadequate without systematic explications of the sources of injustice, including, at least: (1) an analysis of how participants are excluded from the creation of justice-related agendas, as well as decision making regarding policy agendas; (2) the continued exposure of exploitation in labor relations; (3) an examination of the factors leading to the erosion of communities, collective identity, and the right to sovereignty; and (4) the long-term cost to nature (including humans) when justice is defined as separate and subservient to humans.

Diversity cannot be denounced as deviance. Society cannot fail to acknowledge the dialectical nature of the conflict between totalization and particularism, corporate monoculture and bioregional diversity, and abstract universalism and collective indigenous identity. Time (historical setting) and place (comparative setting) have proven that traditional assumptions about the implementation of fairness and equality are inadequate, especially for those individuals who exist at the margins of globalization. A workable theory of justice not only must acknowledge and extend foundational theories, but also must critically evaluate those theories so as not to neglect the fundamental connection.

KAHN, RICHARD F.
1905–1989

British economist Richard Ferdinand Kahn, fellow of King’s College Cambridge (from 1930) and professor of economics at the University of Cambridge (from 1951), was John Maynard Keynes’s (1883–1946) favorite pupil and closest collaborator during the writing of Keynes’s General Theory (1936). Kahn became Keynes’s literary executor and remained the torchbearer of Keynesian theory and policy throughout his life (Pasinetti 1987). Kahn first graduated in 1927 in natural sciences, then switched to economics and was awarded first-class honors in the 1928 Economics Tripos (courses and examinations leading to the Cambridge B.A.). In the following year and a half, he wrote a dissertation on The Economics of the Short Period (1989), which secured him a fellowship at King’s College. Kahn’s dissertation remained unpublished for fifty years, but it contained the essentials of the economics of imperfect competition, which would be refined and extended by Joan Robinson (1903–1983) in her 1933 book, The Economics of Imperfect Competition, as well as the short-period method, which came to form the mold in which the General Theory was cast (Marcuzzo 1994).

Kahn is best known for his discovery of one of the ingredients of the Keynesian revolution, namely, the principle of the multiplier. By this is meant the relation between the increase in any component part of the exogenous aggregate expenditure and the increase in income and employment whenever there are idle resources in the economy, such as undercapacity utilization of plant and machinery and unemployment of labor. In its simple form, it can be stated as follows: if $c$ is the fraction of any increase in income that individuals decide to consume, an increase of, say, $1 in expenditure will generate an increase in income equal to $1/ (1-c).

Kahn presented his result in the midst of the controversy over public investment as a means to fight unemployment; the idea was to show that an increase in public expenditure would be effective in increasing total employment, contrary to the view held at the time that it would simply “crowd out” private employment (Kahn 1931). Its main implication, which is central to Keynesian macroeconomics, is that it is the level of investment that determines savings and not the other way around, as pre-Keynesian economic theories had it.

Besides playing a leading role in the discussions that paved the way to the General Theory, Kahn contributed to extending and clarifying some of its concepts and tools of analysis. His evidence to the Radcliffe Committee on the Working of the Monetary System (Kahn 1959a, 1959b) and his work on the liquidity preference (Kahn 1954) are landmarks in the Keynesian view of monetary theory and policy (Dardi 1994). He also contributed to the understanding of the so-called wage-spiral, built into the process of wage negotiation, in causing inflation (Kahn 1976), and, last but not least, left his mark on the post-Keynesian theory of growth and income distribution (Kahn 1959c).

KALECKI, MICHAŁ
1899–1970
The Polish economist Michał Kalecki was born in 1899 in Lodz and died in Warsaw in April 1970. His academic training was in engineering, and he was self-taught in economics, influenced by writers such as Karl Marx (1818–1883) and Rosa Luxemburg (1870–1919). He obtained his first quasi-academic employment in 1929 at the Research Institute of Business Cycles and Prices in Warsaw. A Rockefeller Foundation fellowship allowed him in 1936 to study abroad in Sweden and then England, where he remained for the next ten years, including employment during World War II (1939–1945) at the Oxford University Institute of Statistics. After working for the International Labour Office in Montreal in 1945 and 1946, Kalecki was appointed deputy director of a section of the economics department of the United Nations Secretariat in New York at the end of 1946. He resigned from the United Nations in 1954 in response to the appointment of a board of directors to exercise control over the World Economic Report, which was seen as resulting from American involvement in the work of the United Nations. Kalecki returned to Poland in 1955, where he was heavily involved in the debates over the role of decentralization and workers’ councils, the speed of industrialization, and the relative size of consumption and investment. In the last decade of his life, Kalecki was heavily involved with problems of economic development.

Kalecki discovered a range of ideas on the importance of effective demand and the role of investment similar to those discovered by John Maynard Keynes (1883–1946), and Kalecki can claim priority of publication (1933 for Kalecki versus 1936 for Keynes). While there are similarities between Kalecki and Keynes, there are also differences—for example, over the determinants of investment and the perception of the economy as competitive or oligopolistic (on the relationship between Kalecki and Keynes, see Sawyer 1985, chap. 9). The school of thought known as post-Keynesianism has been strongly influenced by the work of Kalecki, and many of the ideas current there can be traced back to Kalecki (King 1996 and 2002, chap. 2). Kalecki was influenced by Marx and Marxist writers but would not have described himself as a Marxist (Sawyer 1985, chap. 8).

A key element in Kalecki’s work was the idea that the level of economic activity would be determined by the level of aggregate demand, and that investment decisions were a particularly significant element in the determination of the level of demand. Any decision to increase investment expenditure can only come to fruition if finance is available and provided through the banking system. Actual investment expenditure generates a corresponding amount of savings. Kalecki argued that savings were undertaken predominantly out of profits, and he often assumed as a first approximation that workers did not save, and hence investment expenditure in aggregate determined the volume of profits. As Kalecki wrote, “capitalists as a class gain exactly as much as they invest or consume, and if—in a closed system—they ceased to construct and consume they could not make any money at all” (Kalecki 1990, p. 79). The assumption that wages are spent and the view that capitalists’ expenditure determines their income was reflected in an aphorism that was ascribed by Joan Robinson to Kalecki—“the workers spend what they get, and capitalists get what they spend”
(Robinson 1966, p. 341)—though it cannot be found in the writings of Kalecki. There is also a reverse direction of causation at the level of the enterprise, whereby the profitability of the enterprise will influence its investment decisions. Profits provide internal finance for investment, and the present level of profits influences expectation on future profits.

Kalecki saw capitalism as oligopolistic and monopolistic, and he dismissed the notion of perfect competition as a “dangerous myth.” His approach to pricing put forward the idea of the “degree of monopoly,” which expresses the notion that the market power that an enterprise possesses will strongly influence the markup of its price over its (production) costs. The extent of market power depends on such factors as the dominance of the enterprise in its market, the barriers to entry into the industry, and so on. The degree of monopoly leads to a theory of the distribution of income and of the determination of real wages. At the level of the enterprise, the degree of monopoly sets the price-cost ratio; from this, the ratio of profits to sales can be derived. Further derivation and then aggregation indicates that the share of profits in national income depends on the average degree of monopoly and on the cost of imports. Since wages are a major component of costs, the degree of monopoly has a major impact on the real product wage. Kalecki thus advanced a distinctive theory of the distribution of income between wages and profits, and the view that a firm's pricing behavior, rather than events in the labor market, set the real wage.

The phenomenon of the business cycle was central to Kalecki's economic analysis of capitalism, and his discovery of the importance of aggregate demand for the level of economic activity was undertaken in the context of cyclical fluctuations. Kalecki viewed “the determination of investment decisions by, broadly speaking, the level and the rate of change of economic activity” as the pièce de résistance of economics (Kalecki 1968, p. 263). The central feature of Kalecki's explanation of the business cycle is the influence of investment on economic activity and hence the determinants of investment. Kalecki distinguished between the decision to invest and the placing of orders for investment, with a significant lag between investment orders and actual investment. Investment orders depend on profits, and profits are generated by actual investment.

Kalecki also postulated that investment is negatively influenced by the size of the capital stock. Combining these elements, Kalecki arrived at a mixed differential-difference equation (Kalecki 1990, pp. 82–83), for which there may be many solutions. Kalecki sought to establish that there is one solution for which the amplitude remains constant. “This case is especially important because it corresponds roughly to the real course of the business cycle” (Kalecki 1990, p. 87). He then argued that, with that condition satisfied, the other parameters of the model are such that a regular cycle of around ten years would be generated, which conforms with the general pattern of the time of a cycle of the order of eight to twelve years in length. The mixed differential-difference equation was the basis of Kalecki's attempt to generate a self-perpetuating cycle, which was later to be resolved through the notion of limit cycles.

Another important ingredient of his approach is summarized in the oft-quoted statement that “the long-run trend is but a slowly changing component of a chain of short-period situations; it has no independent entity” (Kalecki 1968, p. 263). This can be interpreted as undermining the predominant equilibrium approach to economic analysis whereby there is a long-period equilibrium around which the economy fluctuates or toward which the economy tends and which is unaffected by the short-period movements of the economy.

The discoveries of Keynes and Kalecki in the 1930s on the principle of effective demand and the associated idea that governments could (and should) manipulate their budget stance to generate high levels of employment (rather than aim for a balanced budget) seemed to open the way for the achievement of permanent full employment in capitalist economies. Kalecki raised many doubts about the possibilities of achieving prolonged full employment in a laissez-faire capitalist economy, most notably the resistance by business to prolonged full employment arising from a loss of “discipline in the factories.”

Kant, Immanuel

1724–1804

Immanuel Kant was born in 1724 in Königsberg, Prussia (now Kaliningrad, Russia). He contributed to metaphysics, epistemology, ethics, and political philosophy. He lived most of his life in Königsberg, where he died in 1804. He lived long enough to see the early stages of the French Revolution, which he initially welcomed because of its emphasis on both liberty and equality.

Kant’s philosophy emphasized the reconciliation of disparate themes and theories. In human nature he tried to reconcile the demands of heteronomy and autonomy. The latter has two distinct meanings: one ethical, the second metaphysical. In epistemology he tried to reconcile the competing claims of the rationalists—who emphasized a priori knowledge, primarily mathematics—with those of the empiricists, who claimed that all knowledge is based on experience. David Hume’s skeptical development of empiricist philosophy, Kant said, “interrupted my dogmatic slumber” (Kant [1783] 1953, p. 9). Humean skepticism threatened both traditional theism and the recently triumphant Newtonian science.

KANT’S COPERNICAN REVOLUTION

Kant wanted to defend religion from skeptical arguments and Newtonian science from a similar type of skepticism. He also defended a libertarian theory of human nature from the new determinism that many saw as implicit in Newtonian physics. This is the problem of heteronomy and autonomy. The former is the view that even human behavior is controlled by the same laws as the rest of the universe, implying that free will is an illusion. The latter is the view that not all human actions are dependent on (or deducible from) the laws of nature.

Kant’s theory of knowledge was based on a complex theory of categories of the mind that we have a priori (prior to, and independently of, experience) and that we apply to experience. Without it we could not have any coherent experience. It constitutes a third way of knowledge between a priori mathematical and logical concepts and those based on experience. It is syntethic a priori knowledge. Just as Copernicus reversed the roles of the sun and earth, so Kant reversed the role of thought and experience: We impose our mental categories on the world, not vice versa.

Kant argued that these concepts applied only to the world of experience and could not apply to metaphysical problems such as God, freedom, and immortality. He produced a complex critique of the three traditional theistic proofs (ontological, teleological, and cosmological) but also argued that reason could not disprove God’s existence, and then offered pragmatic proofs for such a belief. Kant’s Religion within the Limits of Reason Alone ([1787] 1960) was an attempt to replace religion based on revelation or fideism.

MORAL AND POLITICAL PHILOSOPHY

Kant’s moral philosophy was based on an ethical interpretation of autonomy culminating in his categorical imperative(s) and his proto-liberal political philosophy of freedom. The categorical imperative has two versions: “I ought never to act except in such a way that I can also will that my maxim should become a universal law” ([1797] 1964, p. 70) and the somewhat clearer, “act in such a way that you always treat … the person of any other, never simply as a means but always … as an end” ([1797] 1964, p. 96). The best interpretation of this is: “Don’t use people as if they were tools or machines; they are persons with independent wills and desires of their own.” Because Kant assumed that people have conflicting wills and desires, he asserted that legislators must pass laws that protect everyone equally. Kantian equality is purely formal, meaning that laws must protect everyone equally, but he permitted massive material inequality, based on differences in everyone’s “talent, industry, and good fortune” (“Two Essays on Right” [1797] in Phelps 1973). Kant denied that there could be a principle of welfare or happiness, inferring from this that neither morality nor legislation could be based on experience.

Kant distinguished between perfect and imperfect duties. The former are based on the putative rights of others; the latter are not. Therefore, although animals do not have rights, we should not be cruel to them. Charity to the poor is another imperfect duty.

Despite the cosmopolitan character of his categorical imperative and political philosophy, Kant seemed to absorb from Hume an uncritical racism, especially concerning Africans. There are two ways in which one might defend either Kant or Hume. One would be the historicist argument, that we cannot judge people from different times and places by our contemporary standards. The other is to downplay the significance of these views in either philosopher in their overall philosophy. The latter is the more promising route because the eighteenth century was
allegedly the age of Reason and Enlightenment. It also was the age in which slavery was first attacked on a widespread basis, leading to its eventual abolition in most of the world. Jeremy Bentham (1748–1832) argued for decent treatment for blacks, for animals, and (albeit secretly) for homosexuals, on the grounds that the key issue was not “Can they reason?” but “Can they suffer?” In addition, racism seems to conflict logically with Kant's cosmopolitanism.

Kant's greatest influence on the twentieth century may have involved his proposals for perpetual peace via a League of Nations. He also had great faith in republican governments to promote such peace better than monarchies would. In 1784 he wrote “What Is Enlightenment?” The basic idea was a willingness to dare to think for ourselves. His idea of autonomy, however, should not be confused with a “do your own thing” mentality: Instead, it meant that the laws we impose on ourselves are based on logically impeccable arguments.

KARIEL, HENRY S.
1924–2004

Henry S. Kariel was one of the most influential postmodern political scientists of the latter half of the twentieth century and a significant critic of the fundamental concept of pluralism in American politics. Born in Plauen, Germany, on July 7, 1924, Kariel earned his doctorate in political science at the University of California at Berkeley and served primarily on the faculty of the University of Hawaii at Honolulu. Kariel's scholarship vaulted him to the forefront of the “antipluralist” movement that attempted to interpret and describe the political and social unrest of the 1960s and 1970s. He proposed a new methodology of political science rooted in the identification of citizens at the political margins. This was a concerted effort to expand democracy by transforming the disaffected into willing and vital participants within the political process at the expense of the traditional pluralistic tradition.

Kariel was heavily influenced by German philosopher Friedrich Nietzsche (1844–1900), who argued that it was impossible for human beings to attain final knowledge of the political and social realms. Kariel's political science was informed by this brand of postmodern relativism, and he posited that a consistent relativism recognized the claims and ends of all people, rather than those of a pluralistic elite. Established truths were no longer true, especially in rapidly changing social conditions. In this view, what the individual believes to be real is subjective, and the political scientist must therefore question established systems and truths in an effort to understand and make sense of new directions, as well as help create a more direct democracy that serves the needs of all.

Kariel viewed the student protests against the Vietnam War on college campuses, the riots in urban ghettos, governmental scandals, and the general backlash against the pluralistic reliance upon trusted institutions that often characterized the late 1960s and 1970s as evidence of the decline of pluralism and the onset of a new political dichotomy, one that legitimately questioned the authority of government while demanding an egalitarian society. As opposed to the general disturbance among citizens and more conservative academics that such events caused, Kariel and many critics of liberal pluralism saw not wanton violence or decadent protest, but rather a controlled effort aimed at forging a new political and social reality. He thus urged the adoption of “a suspension of the empirical” and looking beyond traditional data-gathering to define and explain new political theory.

While Kariel claimed to not repudiate constitutionalism, his approach was criticized for contradicting the fundamental ideology of constitutionalism. The essential critique of Kariel posited that while the citizenry's flexibility and freedom to act politically are indeed a part of the pluralistic tradition, the sovereign power to govern is limited by the people's own creation—the Constitution. In addition, critics charged that antipluralists such as Kariel...
failed to explain how a society in which everything was politicized would guarantee equitable results. In addition, despite the difficulties of the late 1960s and the demoralizing resignation of President Richard M. Nixon in 1974, citizens were unlikely to abandon the authority vested in governmental institutions in favor of the unknown dynamic for which Kariel argued. Kariel died in Hawaii on July 8, 2004.

**KAUNDA, KENNETH 1924–**

The decolonization decade of the 1960s in Africa produced not only a bevy of territorial successor states, but a crowd of would-be “fathers” of new countries. Most remembered, perhaps, are Kwame Nkrumah (1909–1972) of Ghana, Julius Nyerere (1922–1999) of Tanzania, and Félix Houphouët-Boigny (1905–1993) of Côte d’Ivoire. In the same class, but perhaps less memorable for indiscernible reasons, is Kenneth David Kaunda, who was prime minister and first president of Zambia (formerly Northern Rhodesia) in Central Africa. Kaunda stayed in office for twenty-seven years, peacefully handing over power to an elected successor in 1991. With his country prey to the powerful and white supremacist neighbor, South Africa, painfully dependent on the one major natural resource, copper, and threatened by ethnic strife, Kaunda proved unable to transcend his country’s underdevelopment and vulnerability to division, nevertheless accomplishing the daunting feats of maintaining independence and national integration.

Similar to other emergent civic leaders of his generation, Kaunda was educated in mission schools (his father was a missionary), became a teacher, served on a local council, and plunged into nationalist politics. In 1950 he was secretary of his branch of the Northern Rhodesia African Congress; by 1953 he was secretary-general of the African National Congress (ANC). He served a brief term in prison for a political offense, visited Britain as a guest of the anticolonialist Labour Party, and broke with the ANC in 1958. The politics of the era was dominated by the Southern Rhodesian whites and the British government’s attempt to form a Central African Federation. Resistance to federation resulted in another prison term for Kaunda and then to the formation of the United National Independence Party (UNIP) that delivered independence in 1964 to an ultimately unfederated Northern Rhodesia.

Kaunda’s leadership received popular approval, achieving renewal every five years—in 1988 with 95 percent of the vote—until an ignominious defeat in 1991 in an internationally observed contest. In keeping with the political trend of the era, Zambia banned opposition parties in 1968, became a one-party state in 1972, and declared an official ideology called *Zambia Humanism*, which reflected the “African socialist” fad of the times, as represented by Nkrumah’s *Consciencism* and Nyerere’s *Ujamaa*. Like these two well-known African figures, Kaunda published an autobiography (1962), a volume of speeches (1966), and a guide to his own thinking, *Humanism in Zambia and a Guide to Its Implementation* (1968).
Kaunda’s successor, Frederick Chiluba, treated the country’s founder-president rather shabbily in the post-election period, first attempting to deport him as a “noncitizen” (Kaunda’s father was born in Malawi), then getting the country’s constitution amended to prevent Kaunda from entering the elections of 1996. After accusations of sponsoring a failed coup attempt in 1997, Kaunda retired from politics, devoted himself to good works and his passion for ballroom dancing, and assumed the post of African president-in-residence at Boston University (2002–2004).

Kaunda’s achievements ultimately remain mixed. His writings come across as more diffuse than his contemporaries Nkrumah and Nyerere, although no one doubts Kaunda’s personal integrity. His efforts to negotiate with South African president John Vorster (1915–1983) exposed him to charges of naïveté, although Kaunda was steadfast in providing sanctuary to the (South African) African National Congress in its exile. While avoiding a successful coup—characteristic of West African states in the 1960s and 1970s—Kaunda continually faced sectional and ethnic tensions in the country, despite single-party rule in the 1970s.

As to economic development, Zambia lurched through several programs of rural development and state-led strategies, piling up huge international debts. With copper and cobalt providing 95 percent of the country’s foreign exchange, dramatic drops in international prices from the mid-1970s caused great economic pain, stirring massive opposition among mineworkers, whose union formed the basis of political opposition that ultimately produced the person who ousted Kaunda, Frederick Chiluba.

Kaunda sought help from the World Bank and the International Monetary Fund in the 1980s. One immediate consequence was the fateful maize-meal riots on Zambia’s Copperbelt in December 1986. The Zambian government backtracked; the World Bank and Western governments withheld funds; and inflation, black markets, and internal unrest all ensued. The June 1990 university student protests led to more riots, an announced coup, dancing in the streets, Kaunda contradicting himself on a referendum, and finally a restoration of multiparty government. By 1991 the major opposition party, the Movement for Multi-party Democracy, swept parliament and got Kaunda as president with less than 20 percent of the ballots. Kaunda’s message to his successor included a final contribution to democratic government: “Well, congratulations, you have won… I stand ready to assist you, if you should need my services. For the time being, God bless and goodbye.”

**KEFAUVER, ESTES**

1903–1963

Carey Estes Kefauver was born to Phredonia Estes and Cooke Kefauver July 26, 1903 on a farm near Madisonville, Tennessee. His older brother, Robert, and younger sisters, Nancy and Leonora, rounded out his family. Following a career in law and service in the U.S. House of Representatives (1939–1949) and the U.S. Senate (1949–1963), Kefauver died in Washington, D.C. August 10, 1963. Kefauver attended local public schools, and then entered the University of Tennessee, where he participated in various extracurricular activities. He earned a BA in 1924 but had already begun to study law. After brief service as a teacher and coach in Arkansas, Kefauver entered Yale Law School and was granted an LLB *cum laude* in 1927. He had previously passed the Tennessee bar examination, so Kefauver moved to Chattanooga and joined first a practice set up by his cousins and later another firm, where he became a junior partner in 1930. Civic affairs, work with the Tennessee Valley Authority (TVA), and representation of a local newspaper promoting government reform led Kefauver into political activism, and in 1936 he was narrowly defeated in a state senate bid.

In 1939 Kefauver was appointed state finance and taxation commissioner, served briefly, returned to his law
practice, then entered a special election for Tennessee's third congressional district (Chattanooga) seat upon the incumbent's death. Kefauver won, and was reelected four times; in 1948 he sought a U.S. Senate seat and won a plurality victory in the Democratic primary over the incumbent and a third candidate sponsored by Tennessee's "Boss" Crump. He was reelected in 1954 and 1960, and in intervening years pursued the Democratic presidential nomination. In 1952 President Harry S. Truman and other party leaders offset Kefauver's surprising string of primary victories and delivered the nomination to Illinois governor Adlai Stevenson; the 1956 rematch also produced a Stevenson nomination, but Kefauver's withdrawal in favor of Stevenson late in the campaign encouraged Stevenson to allow convention delegates to select his running mate. Kefauver was nominated, but the Democratic ticket was again defeated in the election, by Dwight Eisenhower.

Kefauver's presidential efforts grew out of his work chairing the Senate's Special Committee to Investigate Organized Crime in Interstate Commerce during the Eighty-first and Eighty-second Congresses. While a congressman, Kefauver had supported Presidents Roosevelt and Truman, the TVA, and government reform and antitrust policy; he sponsored the modern presidential succession statute and supported abolition of the poll tax. Kefauver's involvement in a House investigation of judicial corruption, as well as his personal ambition, underscored by encouragement of some newspaper executives, caused him to see opportunity in a Senate study of organized crime. Events overcame the Democratic Senate leadership's reluctance, and internal Senate politics led to Kefauver's selection as chair when the committee was authorized in May 1950.

The committee held hearings in several cities and began to attract attention as witnesses helped to build a case that criminal elements had developed a national organization substantially rooted in illegal gambling and protected from law-enforcement efforts through bribery and the efforts of friends in useful offices. Public interest in the investigation grew with the publicizing of the connections between racketeers and various public officials, as well as several prominent political organizations; it flourished as hearings first in New Orleans and subsequently in other cities were televised. Committee proceedings were less popular, however, in the White House and in Democratic Senate Majority Leader Scott Lucas's office, as they suggested ties between the Kansas City Democratic organization (President Truman's home base) and gangsters and between Cook County, Illinois, Democrats (Lucas's base) and criminal elements. Kefauver refused to defer study of them, which probably led to Lucas's defeat in his 1950 reelection bid and Truman's opposition to Kefauver's 1952 Democratic presidential nomination quest. The committee's work bore legislative fruit only after the Kennedy administration took office, but several states defeated legalized gambling, and a number of cities established crime commissions in the immediate wake of its reports.

Kefauver had married Nancy Paterson Pigott, Scottish-born daughter of American expatriates and an aspiring artist, in 1935. Daughter Eleanor was born to the couple in 1941, and when other children did not quickly follow, they adopted six-week-old David in 1946. Diane was then born in 1947, and Gail completed the family upon her birth in 1950.

Kefauver fell ill during the summer of 1963 and was diagnosed as having an aortal aneurism; it burst before remedial measures could be taken, and he died at Bethesda Naval Hospital. He was buried in the family cemetery in Madisonville, Tennessee.

KELLEY, HAROLD
1921–2003

Harold Harding Kelley's field of study, social psychology, has been defined variously as the study of attitudes, of groups, or of the ways mental representations shape social behavior and person perception. Hal Kelley contributed to all of these aspects of his field.

Kelley was among the young scholars, including Morton Deutsch (born 1920), Stanley Schachter (1922–1997), and John Thibaut (1917–1986), drawn to the Research Center for Group Dynamics established by Kurt Lewin (1890–1947) at the Massachusetts Institute of Technology (MIT). Kelley's (1950) dissertation research at MIT asked: Do people “key” on particular social information? He found that when a person was described by a list of adjectives, others' attitudes toward that person were especially affected by whether the word warm or cold appeared in the list. Kelley's interest in person perception
was evident again approximately fifteen years later when he coined the term *attribution theory*.

Kelley’s true forte was not empirical research, however; it was theorizing. In his academic appointment at Yale University in the early 1950s, Kelley collaborated with a leading attitude researcher, Carl Hovland (1912–1961), and Irving Janis (1918–1990) to review and synthesize theory and research concerning communication and persuasion.

But it was with John Thibaut, while at the University of Minnesota and later the University of California at Los Angeles, that Kelley developed a prominent theory concerning interpersonal influence in groups. The theory focused on interdependence in the simplest social group—the dyad (two-person “group”). Interdependence implies that the dyad members can benefit or harm one another, and the theory identified bases of mutual influence stemming from patterns of interdependence. Reflexive control constitutes the extent to which dyad members control their own outcomes independent of the other's actions; fate control is the extent to which individuals control the other's outcomes irrespective of the other's actions; and behavior control concerns the extent to which both members of the dyad gain or lose based on the configuration of their actions. For example, when mutual cooperative action is particularly beneficial, or competition is harmful, there is an incentive for each to coordinate with the other's actions, yielding mutual behavior control.

Although the best-known precursors to this theory, by George Homans (1910–1989) and Peter Blau (1918–2002), are labeled *exchange* theories, Kelley rejected this label in favor of *interdependence* theory, because exchange of rewards is just one solution to some of the problems posed by particular interdependence structures. For example, people can reevaluate outcomes or develop sequences of actions (described by *transition lists*) that are more complex than simple exchange.

Kelley probably is best known for work on attribution theory. He proposed that laypeople can be systematic processors of social information, implicitly arraying information in what came to be known as *Kelley’s cube*. This ANOVA model distinguished three types of information that people can use to analyze the causes of others’ (or their own) behavior. For example, when a person uniquely (i.e., low on the consensus dimension of the information cube) and consistently chooses to play backgammon but not, say, chess or checkers (yielding distinctiveness of game-playing behavior), the behavior is attributable to something internal to the person (e.g., a strong preference), and not external (e.g., social convention). Later, Kelley described alternate attribution processes involving cognitive schemas. Hundreds of subsequent studies of attribution, conducted over the next decade, were reviewed by Kelley and John Michela (1980).

In the 1980s and 1990s Kelley helped to build a community of researchers of close relationships (e.g., marriages). One outgrowth, *An Atlas of Interpersonal Situations* (2003), may be seen as a step in the direction of Kelley’s vision that social psychology should develop very general principles—paralleling chemistry’s periodic table, for example—and steer clear of demonstrations of counterintuitive social phenomena that often dominate the field but are neither cumulative nor rich.

Harold Kelley received numerous awards for his contributions, from social psychology societies and from the broader scientific community, as when he was elected to the U.S. National Academy of Sciences.

**KENNEDY, JOHN F.**

**1917–1963**

John Fitzgerald “Jack” Kennedy, the thirty-fifth president of the United States, was born May 29, 1917, in Brookline, Massachusetts, and was assassinated in Dallas, Texas, on November 22, 1963. Jack was the son of Joseph Patrick Kennedy (1888–1969) and Rose Fitzgerald (1890–1995); both grandfathers, Patrick Joseph Kennedy (1858–1929) and John F. “Honey Fitz” Fitzgerald (1863–1950), had been politically prominent in Boston. Jack’s father was determined to see his first born, Joseph...
Patrick Jr., elected president, but Navy pilot Joe Jr.’s death in 1944 caused Joe to transfer his political dreams to Jack.

Jack was an indifferent student at day schools, then in a Catholic boarding school, and finally at Choate, a preparatory school in Connecticut that Joe Jr. was attending. Fellow seniors named Jack "most likely to succeed," and he graduated in the middle of his class. Joe Jr.’s shadow led Jack to attend Princeton University rather than Harvard, but poor health, which plagued his entire life, soon forced him to withdraw. He entered Harvard in 1936 and continued to perform modestly as a student, but public affairs then captured Jack’s attention. He registered for a heavy academic load in the fall of 1937 so that he might travel to Europe in early 1938 to research an honors thesis on contemporary politics. That paper reviewed Great Britain’s prewar policies toward Germany and was published in 1940 as *Why England Slept*; it proved unexpectedly popular in an America unnerved by world events.

War approached, and Kennedy attempted to enter officer candidate schools, but failed the physical examinations. Joe Kennedy Sr., the U.S. ambassador to Great Britain in the late 1930s, arranged through his former naval attaché for Jack to enter the U.S. Navy in late 1941. Kennedy was trained to operate patrol-torpedo boats and was sent to the Pacific, where his boat (*PT-109*) was rammed by a Japanese destroyer in August 1943. Jack led survivors to a nearby island, directed successful efforts to attract a rescue, and later returned to duty, but physical maladies caused his return to the states and his eventual retirement from the Navy.

Joe Kennedy enthusiastically supported Jack’s race for the eleventh Massachusetts congressional district seat in 1946, and after three terms in the U.S. House of Representatives Jack successfully challenged incumbent Henry Cabot Lodge Jr. (1902–1985) for a U.S. Senate seat. Kennedy’s bid for the 1956 Democratic vice-presidential nomination fell just short, and immediately following Dwight D. Eisenhower’s (1890–1969) reelection he mounted a campaign for the 1960 Democratic presidential nomination. Kennedy’s Catholicism was inevitably an issue, but he defused it by asserting the principle of church-state separation. He won the nomination, then defeated the Republican candidate, Richard Nixon (1913–1994), by 120,000 popular votes; the electoral vote was not so close (303–219).

Jack, his wife Jacqueline Bouvier Kennedy (1929–1994), and their young children presented active, sophisticated, optimistic faces to the country. In accepting his party’s nomination, Kennedy had described a “New Frontier” of possibilities for the nation, and his inaugural speech built on that vision. The White House became “Camelot” after the romantic stage version of King Arthur’s reign; the Kennedys were admired as royalty, and it was sometimes suggested that a Kennedy dynasty had begun wherein Jack would be succeeded first by his brother Robert (1925–1968) and then by their younger brother Edward (b. 1932).

Cold War issues hounded the Kennedy presidency, however. A 1961 invasion of Cuba, a Soviet client, at the Bay of Pigs by CIA-sponsored Cuban exiles failed, and it was soon followed by East Germany’s provocative construction of a wall isolating western sectors of Berlin. In 1962 U.S. intelligence efforts revealed that the Soviet Union was basing offensive missiles and long-range bombers in Cuba. Kennedy mobilized the military, authorized complaints in the United Nations Security Council, and ordered the Navy to “quarantine” Cuba to prevent receipt of more weapons. Diplomacy and U.S. willingness to resort to military action caused removal of the arsenal. This incident provided the most dangerous moment of the Cold War.

The “space race” gave Kennedy another means of challenging the Soviets, one that was also infused with domestic policy. Soviet satellites and manned orbital flights embarrassed the United States. Initial American efforts were spectacular failures, but science advisors concluded that a manned moon landing was feasible. Convinced that gaining the upper hand in space would enhance U.S. prestige abroad, restore American confidence, and open doors to technological and economic advances, Kennedy committed the United States to a safe manned flight to the moon and back by the close of the 1960s. His vision was fulfilled in July 1969.

The civil rights movement posed different domestic policy problems. Kennedy had telephoned the wife of Reverend Martin Luther King Jr. (1929–1968) when King was imprisoned during the election campaign; this encouraged many to expect Kennedy to champion civil rights. His administration proved less than they hoped, although it made some efforts to extend voting rights and to reduce employment discrimination. But activists known as “freedom riders,” who were testing Kennedy’s promise to end public-transportation segregation, were violently attacked in Alabama, and the University of Mississippi was awkwardly integrated, causing a deadly riot. Kennedy proposed a sweeping civil rights bill during the summer of 1963, but Congress acted only when Kennedy’s successor, Lyndon Johnson (1908–1973), promoted the bill as a memorial to the slain president.

In November 1963 Kennedy traveled to Texas to end bickering among Democrats there. As his limousine approached downtown Dallas, gunshots fatally wounded him. A government commission headed by Chief Justice Earl Warren (1891–1974) later blamed Lee Harvey Oswald (1939–1963) for the act as a solitary assassin, but...
conspiracy theories abounded. Robert Kennedy and President Johnson were suspicious of the CIA, American mobsters, and Cuban operatives, and Johnson himself was suspected of involvement by some. Oswald's murder as he was being transferred between jails only two days after Kennedy's shooting further fueled misgivings that persisted for decades. Gerald Posner's 1993 book *Case Closed* best refuted conspiracy advocates.

Kennedy was survived by Jacqueline, who later remarried, was again widowed, and died in 1994 of cancer; daughter Caroline, who became a writer, attorney, wife, and mother of three Kennedy grandchildren; and son John Jr., who perished in a 1999 private-plane crash. Another son, Patrick Bouvier Kennedy, had been born prematurely and died within days in August 1963.

Had Kennedy not been murdered, health problems may have prematurely ended his presidency; some suggest that scandals resulting from his dealings with gangsters and a succession of female acquaintances would have brought down his administration. The Vietnam War may have ended sooner under Kennedy's leadership, but that may have delayed the eventual Soviet collapse and slowed establishment of Chinese-American relations. Civil rights legislation may have been slower and more limited, and America's baby boomers may have become more constructively active and less cynical and distrustful. The more positive vision suggests that a "normal" Kennedy presidency could have forestalled many of the political traumas that later plagued the United States, along with the personal, combative political style that they engendered.

**KENYATTA, JOMO**

1893–1978

Jomo Kenyatta, also known as Mzee Jomo Kenyatta, is considered the founding father of the independent nation of Kenya. He became Kenya's first prime minister (1963–1964) and first president (1964–1978). Acknowledged as a fascinating and courageous leader, his controversial life began when he was born to Muigai and Wambui as a member of the Kikuyu people. His birth name was Kamau wa Ngengi. His parents died while he was a young boy, and he spent time in his youth working with his grandfather, who was a medicine man steeped in the Kikuyu tradition. Kenyatta married his first wife, Grace Wahu, in 1920. They had two children, a daughter and a son.

Kenyatta entered local politics in 1924 when he joined the Kikuyu Central Association (KCA). He created and began to edit a monthly journal for the KCA known as *Muisgwihanja* (The Reconciler) in 1928. Much of the writing in this journal was focused on cultural nationalism, unity, and moral ethnicity for the Kikuyu people. He also focused heavily on campaigning for land reform, ownership rights, and political rights for African people. The KCA sent Kenyatta to London to lobby for Kikuyu rights, and in 1931 he enrolled in Woodbrooke Quaker College in Birmingham, England. He later attended the Comintern School in Moscow, then returned to London to study at the University College London and the London School of Economics (LSE). He focused on social anthropology and economics, and published his LSE thesis in 1938 as his first book, *Facing Mount Kenya*, an ethnography of the Kikuyu people penned under the name Jomo Kenyatta. He was briefly married to Edna Clarke during this period, and she gave birth to his son in 1943.

In England, Kenyatta had many friends and associates, and formed the Pan-African Federation with Kwame Nkrumah (1909–1972) in 1946. He then returned to his homeland and became the principle of Kenya Teacher's College and president of the Kenya African Union (KAU). Upon his return to Kenya, he married Grace Wanjiku in 1946. She died in childbirth in 1950 after giving birth to a daughter. The following year, he married his fourth wife, Ngina Kenyatta, to whom he would remain...
married for the rest of his life. They had four children together.

On October 20, 1952, Kenyatta was arrested by the British government and charged with being a manager and member of the society of Mau Mau. The Mau Mau revolution was a lengthy battle of the Kikuyu people against British control. Kenyatta denied any participation and countered that he spoke out against the Mau Mau because they were not working with the KAU. After a lengthy trial in 1953, Kenyatta was convicted and imprisoned for six years in Lokitaung, a region in northwestern Kenya. He was later sent into exile. While in exile, he was elected president in absentia of the Kenya African National Union, which later joined with the Kenya African Democratic Union to become one party. Kenyatta was released by the British government, and returned to government in 1961. He was instrumental in forming a parliamentary body, instituting a new constitution, and creating the republic of Kenya. Kenyatta is heralded as a great leader. He was also a noted author, publishing numerous books and pamphlets, including *My People of Kikuyu and the Life of Chief Wangombe* (1944), *Suffering without Bitterness* (1968, a biography), *Kenya: The Land of Conflict* (1971), and *The Challenge of Uhuru: The Progress of Kenya. 1968 to 1970* (1971). He died in his sleep in Mombasa in 1978.

KEOHANE, ROBERT

1941–

Robert Owen Keohane is an American political scientist and an expert in international relations. He is most well known for his insistence on the importance of international institutions in shaping state behavior. Keohane challenged the stress of many political scientists on unitary actors and on the conflictual tendencies of anarchy; he simultaneously shifted the focus of the discipline away from security studies and toward economic policies and relationships.

In turning to economic policy in his early work in the 1970s, Keohane saw that this arena involved the interaction of political actors within states in behaviors that cut across states. This observation challenged the unitary actor assumption, a key element of the “realist” school, which treats states as unitary wholes, preoccupied primarily with the problem of national security, which is seen largely in military terms. The concepts of “transnational relations” and “complex interdependence,” which Keohane developed with political scientist Joseph Nye, replaced the unitary actors with networks of firms and interest groups operating within and across borders, and offering conflicting pressure on decision makers to define “national interest.” Keohane argued that national governments are players in a policy arena, but their control is by no means exclusive, nor total. Regimes (a mixture of norms and institutions cutting across states) shape state behavior and policy outcomes.

Keohane and Nye pointed out the decline of force as the exclusive issue area, the importance of international regimes, and the fragmentation of authority in each state and thus in their interactions. From 1974 to 1980, Keohane served as editor of *International Organization,* a scholarly journal on international affairs, and transformed it from a largely descriptive and evaluative publication into a significant vehicle for social science and peer-reviewed research.

In the 1980s Keohane shifted his attention away from the fragmented, national-actor arena of domestic politics toward a debate on the international system with the political scientist Kenneth Waltz. Whereas Waltz theorized that anarchy was the root of conflict, because the logic of self-help created a security dilemma (in protecting oneself, one antagonizes others), Keohane argued that cooperation could take place among units in anarchy under the right conditions. According to Keohane, international institutions could solve the problems of coordination and information that inhibit cooperation. These institutions would not be supranational—that is, they do not impose rules from above, but arise out of voluntary participation.

Drawing on research in game theory and institutional economics, Keohane argued that institutions make it easier to share information, reduce transaction costs, facilitate bargains across issue areas, provide mechanisms for dispute resolution, and supply processes for making decisions. Institutions can increase cooperation even without coercive power. Institutions may increase iteration—that
is, the number of interactions among units—thus generating a positive cycle of cooperation. The debate between Keohane’s neoliberal institutionalism and Waltz’s neorealism structured the field for many years.

Three lines of inquiry challenged the centrality of the Keohane-Waltz debate. First, the domestic politics school, whose members generally were sympathetic to Keohane’s critique of Waltz, complained that by moving the debate toward system arguments—cooperation versus conflict by unitary states under anarchy—the domestic political elements of international politics were being neglected. These writers wanted to continue the disaggregation of the unitary state, which Keohane had begun to do in the 1970s, by exploring the role of domestic politics in shaping how states defined their position in the world. A state’s position in the international system is open to rival interpretations. The issue of whether a state wants to cooperate turns on domestic politics, on whether there is support at home for international cooperation, and on whether the supporters are able to prevail in policy debates.

The second line of inquiry, forwarded by constructivists and sociological theorists, complained that both Keohane and Waltz neglected nonrationalist and nonmaterial aspects of the interaction of units. Keohane accepted, after all, Waltz’s assumption that states were utility maximizers. What he disputed was what maximization under anarchy led to; under the right conditions, according to Keohane, it led to cooperation, not the inevitability of conflict. But neither Keohane nor Waltz paid much attention to such aspects as culture, ideas, values, the internalization of norms, the constitutive elements of identity, and the tissue of human exchanges and cultures, which structure interaction.

A third line of inquiry, advanced largely by security specialists, attacked Keohane’s emphasis on institutions, on the way these operate, and on the neglect of security issues, generally and in relation to the functioning of institutions. Some specialists in this camp are realists who agree rather more with Waltz, while others disagree on agenda, the evaluation of interests, the actual prospects for cooperation, and the implications for public policy.

**KERNER COMMISSION REPORT**

From 1965 through 1968, a total of 329 racial disturbances erupted in 257 U.S. cities, causing 300 deaths and millions of dollars in property damage. In summer 1967 rioting broke out in several cities, causing 84 deaths and an estimated $75 to $100 million in property damage. Federal troops had to be brought in to quell the disorder. In Detroit alone, in 1967 43 people died and 1,383 buildings were burned. Alarmed, on July 28, 1967, President Lyndon Johnson created the National Advisory Commission on Civil Disorders, commonly known as the “Kerner Commission” after its chairman, Otto J. Kerner Jr., the governor of Illinois, to investigate the causes of the civil disturbances and to provide recommendations for the future.

The other members of the bipartisan commission appointed by President Johnson included John Lindsay, the mayor of New York; Senator Fred R. Harris,
Democrat of Oklahoma; Representatives James C. Corman, Democrat of California, and William M. McCulloch, Republican of Ohio; I. W. Abel, president of the United Steelworkers of America; Roy Wilkins, director of the National Association for the Advancement of Colored People; Senator Edward W. Brooke, Republican of Massachusetts; Charles B. Thornton, chairman of Litton Industries, Inc.; Katherine Graham Peden, Kentucky’s commissioner of commerce; and police chief Herbert Jenkins of Atlanta. A large staff headed by David Ginsburg, a Washington, D.C., lawyer, was drawn from the liberal establishment that had supported the civil rights movement. The 426-page report, issued on February 28, 1968, quickly became a best seller, selling more than 2 million copies, and influenced thinking on race relations in the United States for the forthcoming decade.

President Johnson suspected that a political conspiracy was responsible for encouraging black urban militants to incite racial uprisings. But the commission found no evidence of a political conspiracy; instead, it blamed the racial upheavals on the frustrations and grievances of inner-city blacks, which were caused by persistent economic deprivation and racial discrimination. The most frequently quoted sentence from the report warned that the United States was “moving toward two societies, one black, and one white—separate and unequal” (National Advisory Commission on Civil Disorders 1968a, p. 1). The problems of racial discrimination, poverty, high unemployment, poor schools, inadequate schools, poor health care, and police bias and brutality were cited as major contributing factors to the United States’ racial apartheid. Unless these problems were remedied, the report predicted, the racial divide in the United States would widen. The commission called for sweeping reforms: a large increase in federal aid to cities, a federal jobs program, a system of income supplementation, and an increase in the minimum wage.

None of the proposals were implemented during the Johnson administration, and they were largely ignored after the election of President Richard M. Nixon in 1968. Martin Luther King Jr. hailed the report as a “physician’s warning of approaching death, with a prescription for life.” (Report of the Select Committee on Assassinations, U.S. House of Representatives 1979, pp. 356-357.) Critics, though, argued that by blaming the problems of the black community on white racism, the report spawned an enduring sense of black victimization and hopelessness.

KEY, V. O., JR.
1908–1963

V. O. Key Jr., one of the United States’ greatest political scientists, pioneered the study of elections, political parties, and public opinion, and left a remarkable collection of books and articles despite a career cut short at age fifty-five. His Southern Politics in State and Nation (1949) analyzed in penetrating fashion the confusing, little-understood political arrangements of the one-party Democratic South using innovative, intelligible techniques of electoral analysis. Noting that in “its grand outlines, the politics of the South revolves around the position of the Negro” (1949, p. 5), Key went on to show that the big losers in the region’s odd political system were “those who have less,” of both races.

Likewise, his masterful Public Opinion and American Democracy (1961) offered invaluable theoretical insights into the elusive role of public attitudes in the governing process, elucidating the all-important linkage between what governments do and what the people think. “If a democracy tends toward indecision, decay, and disaster, the responsibility rests [with its political leaders], not in the mass of the people” (1961, p. 558), he concluded.

Key grew up in the West Texas town of Lamesa, where his father was a prominent lawyer. After earning a BA and MA at the University of Texas, he studied at the University of Chicago from 1930 to 1934 under Charles Merriam, an advocate of a “new science of politics,” earning his PhD in 1934. After two years of teaching at UCLA and a year each working for the Social Science Research Council in Chicago and the National Resources Planning Council in Chicago and the National Resources Planning
Board in Washington, D.C., Key assumed his first long-term faculty position, at Johns Hopkins University in 1939. There he immediately launched into writing his influential, path-breaking textbook *Politics, Parties, and Pressure Groups,* which appeared in 1942 and went through five editions. His colleagues hailed the book; Charles Beard wrote to the author that his “bully” book “gleams with humor well concealed” (quoted in Lucker 2001, p. 49). Key made political power the book’s central theme, telling the publisher in his 1939 proposal that “all of what we call political phenomenon can be interpreted” around this concept, adding: “By imaginative treatment, these dry-as-dust matters could perhaps be made, if not to sparkle, at least gleam” (quoted in Lucker 2001, pp. 43–44). Therein lies an element of Key’s success: He matched insightful analysis with an engaging writing style.

Key remained at Johns Hopkins University for a decade, broken only by wartime service at the Bureau of the Budget. Yale University lured him away in 1949, but two years later he moved to Harvard, where he operated at the pinnacle of his discipline for the last twelve years of his life. In the *Journal of Politics* in February 1955 he published his most famous article, “A Theory of Critical Elections,” which called attention to a type of election “in which the decisive results of the voting reveal a sharp alteration of the pre-existing cleavage within the electorate” (p. 4). The article gave birth to an enduring subfield—the study of electoral realignments.

Always at the forefront of his discipline, Key mastered the new techniques of survey research in the late 1950s, taking up residence at the University of Michigan to work with the National Election Studies, then in their infancy. “To speak with precision of public opinion,” he asserted at the outset of his resulting 1961 book, *Public Opinion and American Democracy,* “is a task not unlike coming to grips with the Holy Ghost” (p. 8). But in 550 well-crafted pages, Key captured the elusive topic, locating it firmly within the political process.

At the time of Key’s death in 1963, he was at work on a massive study of the voting process. Using Key’s incomplete manuscript, his student Milton C. Cummings published *The Responsible Electorate* in 1966. The central theme of this slim volume is that voters exhibit an impressive amount of rationality in light of the choices they face, a notion still widely quoted using Key’s apt phrasing: “Voters are not fools.” If he had lived to complete the work himself, there is no doubt he would have produced a weighty study comparable to his last classic, *Public Opinion and American Democracy.*

**KEYNES, JOHN MAYNARD**

**1883–1946**

The doyen of Cambridge economists, bursar of King’s College, and eventual Baron Keynes of Tilton, John Maynard Keynes was a leading member of the Bloomsbury Group, an astute collector of the writings of Isaac Newton (1642–1727), a long-time editor of the *Economic Journal,* a U.K. government policy advisor of significant magnitude, and the main instigator of a revolution in economic theory that created an approach (Keynesianism) that came to dominate Western economic discourse from the end of World War II (1939–1945) until the mid-1970s.

Keynes was undoubtedly the most famous and influential economist of the mid-twentieth century. His 1936 book *The General Theory of Employment, Interest, and Money* is often cited as the single most important book in economic theory published in the interwar period, and it could reasonably be said to have created modern macroeconomics. One graphical representation of the economy that came out of this book—IS-LM analysis—became a staple of textbook economics for many years to come, even though it was later shown not to originate from Keynes’s work alone, but from one individual’s particular interpretation of it. Keynes’s interventionist proposals for helping to regulate the aggregate level of employment

through demand management remained in use in various forms for decades after World War II, and his policy advice on financing both World War I (1914–1918) and World War II was crucial to enabling Allied victories on both occasions. Some of his pithy aphorisms, such as “in the long run we are all dead,” have become legendary.

Despite his undoubted great influence on economics, his legacy is highly controversial. Criticized from the right for advocating inflationary financing, and from the left for attempting to rescue capitalism rather than replace it, the demise of Keynesianism as the dominant force in mainstream economics is usually dated to the mid-1970s, when inflation combined with high unemployment to produce stagflation, something that Keynes had not predicted. Despite such unforeseen developments, his influence still remained active through a number of heterodox approaches to the subject, such as post-Keynesian economics and even new Keynesianism. Like all truly great intellectuals, fresh interpretations of his work are periodically presented, and neglected aspects of it are continually rediscovered.

BIOGRAPHY
Maynard Keynes (as he was known to his friends) was the son of John Neville Keynes (1852–1949), also a well-known economist and the author of The Scope and Method of Political Economy (1891). Maynard Keynes experienced an elite education at Eton and then studied at King’s College Cambridge, where he was appointed to a lectureship in economics after a period working in the British Civil Service. He was soon involved in providing policy advice on financial affairs in India, which then developed into governmental service in the U.K. Treasury regarding the financing of World War I. He was the main Treasury representative at the signing of the Peace Treaty at Versailles, and after the war he strongly criticized the level of the reparations demands made on Germany. In the early 1920s, he argued that Britain should not return to the prewar gold standard system, and if it did, it should not be at prewar parity. In both these instances, his advice was ignored, but in retrospect his judgment has appeared correct to many commentators. By the end of the 1920s, Keynes was supporting David Lloyd George’s (1863–1945) call for a program of government-funded economic expansion of around 2.5 percent of national income per year, in order to cure persistent unemployment.

In addition to his economic works, Keynes published A Treatise on Probability (1921), which provided a critique of the frequency conception of probability then in vogue. Instead of this approach, Keynes favored a logical conception in which probability was seen as being relative to human knowledge, rather than being taken as a given fact of nature. He also published various essays on political matters and even some biographical sketches. In an essay on his early beliefs, he stressed the significance of the British philosopher G. E. Moore’s (1873–1958) Principia Ethica (1903) to the formation of his general attitudes. Keynes had interpreted Moore as applying logical analysis to such areas as feelings, sense-data, and morality, and he later described such an approach as “sweeter air by far” than Sigmund Freud (1856–1939) or Karl Marx (1818–1883). During World War II, Keynes again successfully served in the U.K. Treasury, where he coordinated his activities closely with the U.S. government. He died in 1946, a year after the war ended.

ECONOMIC THEORY
Keynes is best known for introducing into the vocabulary of economists concepts such as the marginal efficiency of capital, liquidity preference, effective demand, the multiplier, and the propensity to consume. He also developed more rigorous definitions of the basic elements of economic analysis, such as income, savings, and investment. However, it is important to realize that Keynes was not working in isolation; instead he actively participated in debates that occurred throughout the 1920s and 1930s among British economists such as D. H. Robertson (1890–1963), Richard F. Kahn (1905–1989), R. G. Hawtrey (1879–1975), and Joan Robinson (1903–1983). Consequently, what precisely is taken to constitute the “Keynesian revolution” in economics is an essentially disputed topic. Keynes himself emphasized that the revolution was directed against the classical theory of employment, but his account of this theory through the work of the economist A. C. Pigou (1877–1959) was itself controversial. Keynes argued that the classical approach only allowed for the existence of frictional and voluntary unemployment, and denied the possibility of involuntary unemployment. Given the context of the Great Depression of the 1930s, Keynes implied that this approach was unrealistic, and set about showing how capitalism could generate significant levels of involuntary unemployment when certain conditions were met.

Keynes presented effective demand (aggregate demand backed by money) as the key concept of his general theory. He asserted that the volume of total employment was determined by the interrelation of aggregate supply and aggregate demand. As opposed to the classical doctrine, in which supply was said to create its own demand (Say’s Law), Keynes suggested that in reality an increase in supply did not necessarily lead to a corresponding increase in demand. This was because when employment increased, aggregate real income also increased. However, due to the psychological factors involved (the propensity to consume), when income increased so also

260 INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION
did consumption, but (crucially) by not as much as income. In order to cover this deficit, an increase in investment sufficient to absorb the excess was required, but there was no guarantee that the necessary level of increased investment would naturally follow. Keynes outlined that the amount of investment was actually dependent on the inducement to invest, which in turn was determined by the relation between the marginal efficiency of capital and interest rates.

Keynes defined the marginal efficiency of capital as being equal to the interest rate that would make the present value of the future returns from a capital good equal to its supply price, and hence it depended on expected returns. Keynes further outlined how the marginal efficiency of capital declined as investment in any particular capital good increased. Given this declining schedule and with any given rate of interest, there was no reason to assume that actual investment would correspond to the amount required to cover the deficit between increased income and consumption. Thus the level of effective demand required to ensure full employment was not necessarily created by the self-adjusting mechanisms of a market economy. Put another way, the economic system did not automatically generate full employment.

To explain the unusual duration of the Great Depression, Keynes suggested that in the 1930s the marginal efficiency of capital was actually much lower than it had been in the nineteenth century, and hence the rate of interest that would generate higher employment levels was unacceptable to many owners of accumulated wealth. To explain the heightened amplitude of depressions, Keynes christened the ratio between an increment of investment and increased income the investment multiplier, and suggested that a multiplier greater than unity accounted for how relatively small fluctuations in investment could generate much larger fluctuations in employment. Keynes concluded from this analysis that investment was promoted by low rates of interest and that this would be facilitated by the disappearance of the rentier class within capitalism.

The “Keynesian revolution” was not only directed against classical economists, but also against Keynes’s earlier approach, which had preached adherence to the framework provided by the Cambridge version of the quantity theory of money. In this respect it is necessary to consider Keynes’s major works in economics published prior to The General Theory. His first book was Indian Currency and Finance (1913), which provided an analysis of the operation of the gold-exchange standard. This was followed by The Economic Consequences of the Peace (1919), an attack on the terms of the Versailles Peace Treaty, and a Tract on Monetary Reform (1923), dealing with the problems of postwar inflation. These books, although undoubtedly important in practical terms, were less significant in terms of providing innovations in pure theory. The Treatise on Money (1930) was Keynes’s most significant work in economic theory prior to The General Theory. Here Keynes emphasized the importance of the behavior of the banking system to understanding fluctuations; by controlling credit, banks necessarily controlled aggregate expenditure. Booms and slumps were thus the result of the oscillation of the terms of credit about their equilibrium position, defined as occurring when savings equaled investment. Disequilibrium was possible in this model as international influences adversely affected the domestic banking system, causing the terms of credit to move above or below their equilibrium level at any given time. The difference between this type of analysis of trade cycles and that given in The General Theory was significant; in the latter, emphasis was transferred away from monetary factors to psychological propensities and expectations of future yields on investment goods.

THE CONSEQUENCES OF KEYNES

Keynes’s new economics, brilliant though it undoubtedly was, was not without flaws. The abstract concepts that Keynes deployed with such aplomb were sometimes ambiguous, and his use of them produced much ongoing debate. Milton Friedman’s A Theory of the Consumption Function (1957) was devoted to empirically investigating Keynes’s psychological rule of increased savings (in percentage terms) as income rose. Friedman concluded that Keynes was mistaken in his presentation of the nature of the propensity to consume, as the ratio between income and savings was the same for all levels of income, but depended on other factors, such as interest rates and the ratio of wealth to income. Friedman later led the monetarist counterrevolution against the Keynesian approach. There was also a question over how “general” Keynes’s General Theory actually was. Since it was designed in part to explain the historical circumstances of the 1930s, was its relevance limited only to the interwar period?

Despite such ambiguities, the impact of The General Theory on Western economics immediately after 1936 was so great that it swept aside the valuable contributions of contemporary economists like Joseph Schumpeter (1883–1950), whose monumental work Business Cycles (1939) found little direct resonance in the West due, at least in part, to the phenomenal success of Keynes’s book. Keynes also became involved in a debate over the importance of the new econometric methodology (as developed by the Dutch economist Jan Tinbergen [1903–1994]) to economic analysis. Keynes was highly critical of the extensive use of mathematical models in economics being promoted by the econometricians, but his reservations were quickly swept aside. Ironically, it was the success of the
Keynesian IS-LM model that added some impetus to the drive for econometric modeling.

The Keynesian system was for many years after World War II hailed by the Left as proof of the inadequacies of capitalism as an economic system and the necessity of increased state control of the commanding heights of the economy. Keynes himself saw his work as a means of improving the internal mechanics of the free-market system, and he criticized state socialism as inefficient and as too restrictive of individual freedoms. Keynes traveled to the USSR on a number of occasions, but he found the fanatical zeal of the Bolsheviks toward Marx’s Capital to be incomprehensible. He declared support for significant inequalities of wealth and income, but not to such a degree that it would impede the entrepreneurial function. Yet he disputed the argument that enlightened self-interest always operated in the public interest, and he saw an important role for the directive intelligence of society organized as a whole exercising some control over private business.

Given the level of his fame and the degree of his policy influence, Keynes’s private life and general views have come under some scrutiny. Early in his life he had intimate relationships with male suitors (such as Duncan Grant [1885–1978], the Bloomsbury painter), but he went on to marry a Russian ballerina in 1925, his “conversion” to heterosexuality being the cause of some friction between members of the Bloomsbury set. He has been accused of “soft” anti-Semitism and also of not realizing the full consequences of his policies of war finance for less developed countries like Russia. Despite such criticism, Keynes’s status as one of the most important economists since Adam Smith (1723–1790) remains unshaken, and his legacy of bringing greater sophistication to economic theory is an enduring one. It seems unlikely that any individual economist could replicate Keynes’s pervasive influence over the subject in the future.

KHMER ROUGE

The Khmer Rouge (Cambodian for “Red Khmer”) was a Communist regime that ruled Cambodia from April 1975 to January 1979. The group, led by Pol Pot, was formally the Communist Party of Kampuchea. In trying to reach its ambitious agricultural production goals and to protect itself against opposition, the regime worked large numbers of people to death and slaughtered its perceived opponents. Characterized by extreme brutality, the regime was responsible for the deaths through slaughter, starvation, overwork, and disease of 1 to 1.7 million Cambodians of a pre-1975 population of 7 or 8 million.

Under the Khmer Rouge, the cities were emptied; industry virtually halted; money, markets, and religion extinguished; and the entire populace sent out to agricultural labor camps in the countryside. Despite the regime’s notional commitment to creating a classless society, in practice, people were divided into “base people,” those who had been under the Khmer Rouge before April 1975 and “new people,” those who came under the regime’s control only with the final victory. New people suffered particularly in the austere rural labor conditions. Food was inadequate, the work schedule was harsh, and medical facilities and medicine were almost nonexistent. Gradually, the family unit was broken up; from 1977 dining was communalized.

The regime slaughtered officials from the old regime, intellectuals (which included teachers), Buddhist monks, and uncovered “enemies.” The Santebal internal security service kept meticulous records of the tortures and executions in which it engaged, Phnom Penh’s S-21/Tuol Sleng facility being the pinnacle of the regime’s torture camps. Failures to achieve the regime’s unrealistic economic goals...
were blamed on internal and external conspirators. Confessions of sabotage were wrung from Cambodians who were forced to name their accomplices, drawing more innocents into the regime’s web of terror. Cambodia’s numerous mass grave sites have come to be known as the Killing Fields.

Khmer Rouge thought placed particular attention to the idea of Khmer purity. Non-Khmer Cambodians of Vietnamese, Chams (Muslim), or Chinese descent faced particular threats. The young were considered especially pure by the Khmer Rouge, as they had not been tainted by the attitudes of the past (Pol Pot’s Little Red Book cites the following Khmer Rouge slogan: “Clay is molded while it is soft”). Society was supposed to start afresh from the “year zero.”

Heavily influenced by the ideas of Mao Zedong of China, Cambodia’s Communist leaders believed they could substitute human willpower for other economic inputs, thus carrying out a “super great leap forward” and revolutionizing agricultural production. The need to continually write one’s autobiography and correct errors of thought were also borrowed from the Chinese Communists. Self-reliance was a core value and, with the exception of supporter China, the regime was effectively closed to the outside world.

In 1979, the Khmer Rouge was ousted from power by a Vietnamese invasion. The regime’s remnants fled to the Thai border and continued to control territory and followers into the 1990s. A United Nations (UN)—organized election in 1993 marginalized the group, which boycotted the polls. By 1996–1997, primarily through defections to the new government, the Khmer Rouge was virtually nonexistent. A show trial of Pol Pot was held in the Khmer Rouge–controlled zone of Cambodia in 1997, and the former leader was put under house arrest. He died in April 1998. In conjunction with the UN, Cambodia agreed in 2003 to set up a mixed Cambodian/international tribunal to bring remaining top Khmer Rouge leaders to justice for their crimes while in power, including Ta Mok, known as “the Butcher,” and Comrade Duch, the head of the S-21 camp.

KHOMEINI, AYATOLLAH RUHOLLAB 1902–1989

Ayatollah Ruhollah Khomeini was the leader of the Islamic Revolution in Iran. He was born on September 24, 1902, in the western Iranian town of Khomein to a clerical family. His father Mustafa was murdered by bandits when Khomeini was five months old. His older brother Sayyid Murtaza (later known as Ayatollah Pasandida) assumed responsibility for Khomeini’s education after their mother died in 1918.

At nineteen, Khomeini traveled to nearby Arak, where he studied religion under Ayatollah Abd al-Karim Ha’iri, a well-known Islamic scholar. Khomeini followed Ha’iri to the Fayzieh madrasa (religious college) in Qom coinciding with the rise of Reza Shah, who curtailed the influence of the clergy as he centralized authority.

In 1932 he married the daughter of a prominent Tehran cleric and had seven children, five of whom survived infancy. Both sons died under mysterious circumstances—his eldest son Mustafa in Najaf in 1977 and his youngest son Ahmad died in Tehran in 1995.

Khomeini published his first tract on spiritual philosophy at age twenty-seven. His reputation as a teacher of fiqh (Islamic jurisprudence) grew throughout the 1940s and 1950s. He published his first major book, Kashf al-
Asrar (“Secrets Revealed”), in 1944, to refute an influential antireligious pamphlet published several years before.

Khomeini catapulted to the national stage in 1962 after he publicly opposed a government reform package that included land reform, women’s suffrage, and a provision which would allow the religious minority Baha’is to seek office. He was a master of rhetoric and coalesced an opposition including traditional clergy, nationalists, and the poor. After Khomeini denounced the Iranian government on June 5, 1963, the shah ordered his arrest, but he was soon released because of popular pressure. After two more arrests, on November 4, 1964, the shah exiled Khomeini to Turkey from where he made his way to Najaf.

It was during his Iraqi exile that, in 1970, Khomeini wrote Hukumat-i Islami (Islamic government) that outlined his theory of vilayat-i faqih (guardianship of the jurists) in which he countered the traditional Shi’ite opposition to direct clerical rule. Khomeini’s followers smuggled many of his sermons into Iran by audiocassette.

Protests erupted on January 7, 1978, after a state-controlled newspaper questioned Khomeini’s sexuality and patriotism. Police fired onto the crowds, beginning a cycle of escalating demonstrations. In October 1978, Khomeini flew to France where he received Iranian visas and the Western press. The shah fled Iran on January 16, 1979. On February 1, 1979, Khomeini returned to Iran and, two months later, declared the Islamic Republic. As supreme leader (rabbar) and against the backdrop of the U.S. hostage crisis and Iran-Iraq War, he launched a cultural revolution and consolidated his power in a series of bloody purges. Khomeini died on June 4, 1989.

KHRUSHCHEV, NIKITA
1894–1971

Nikita Sergeyevich Khrushchev, born into an illiterate peasant family in Kalinovka, Russia, rose through the Communist Party ranks to become the third leader of the Soviet Union. An activist from his teenage years, and a political commissar with the Bolshevik forces during the Russian Civil War, Khrushchev joined the Communist Party of the Soviet Union in 1918. After studying at Kharkov University, he undertook a series of political assignments, which gained the attention of top party leaders in the Ukraine (see Smith 1992). In 1931 Khrushchev moved to Moscow, where he served as secretary of the Bauman district party organization. He became first secretary of the Moscow party organization in 1935.

By 1938 Khrushchev had become a member of the Politburo and went on to serve as first secretary in the Ukraine, where he oversaw the Ukrainian party organization’s purges. He fought in World War II (1939–1945) and afterward became chairman of the Ukrainian Council of Ministers. Other notable positions held by Khrushchev include first secretary of the Moscow City Party Committee (1949), member of the Central Committee Secretariat responsible for supervising party affairs in the various republics, and full member of the Presidium, which well situated him for ascension to the Communist Party’s top leadership after the death of Joseph Stalin in 1953. Khrushchev almost immediately espoused a plan for reforming the economy and stimulating agricultural output. For example, the Virgin Lands program called for plowing up virgin prairie lands in the Caucasus regions, Siberia, and the Volga Basin, and planting corn to use as feed to expand beef production. The plan, a dismal failure, coupled with other failures and leadership challenges, had an impact on Khrushchev’s popularity (see Breslauer 1982).

In 1956 Khrushchev launched a de-Stalinization campaign as a means to shore up his popularity, but it also enhanced the rule of law in Soviet society. The de-Stalinization campaign called attention to a series of Stalinist abuses and breaches of power that included establishing a personality cult, orchestrating purges that terrorized innocent people, and violating the Leninist principle of collective leadership. Khrushchev’s campaign and reforms also yielded unintended results, as exemplified by the burst of artistic creativity, strikes, demonstrations, and political reform efforts in Eastern Europe. This aside, he also sought to reduce the Soviet Union’s isolation in the world.

Khrushchev was the first Soviet leader to advocate “peaceful coexistence” with the West, and the first Soviet leader to visit the United States. In 1959 he met with President Dwight D. Eisenhower (1890–1969) at Camp David, traveled to Iowa to learn about hybrid corn, and toured IBM and Disneyland. The path to improved relations was, however, short-circuited by the 1960 U-2 affair, the 1961 U.S.–sponsored Bay of Pigs invasion, and the 1962 Cuban missile crisis. Interestingly, Khrushchev’s
public persona, as exemplified by heated exchanges with Richard Nixon (1913–1994) during the so-called kitchen debate in 1959, his shoe-banging demonstration at the United Nations in 1960, and communications with John F. Kennedy (1917–1963) during the Cuban missile crisis, most likely contributed to his downfall and banishment from Soviet politics.

KILLING FIELDS

Killing Fields, the term for Cambodia’s mass grave sites, has become synonymous with the country’s Khmer Rouge regime that ruled Cambodia from 1975 to 1979. In trying to reach its ambitious agricultural production goals and to protect itself against opposition, the regime worked large numbers of people to death and slaughtered its perceived opponents, resulting in the deaths of between 1 and 1.7 million individuals of a pre-1975 population of 7 to 8 million.

Agricultural production was key to the Khmer Rouge’s plans for Cambodia’s transformation. The entire population was transferred to state-run farms where food was inadequate, medical attention sparse, and working conditions harsh. The population was exhorted to produce the unrealistic quantity of “three tons [of rice] per hectare.” Many of those who died under the Khmer Rouge died from overwork. Failure to work hard enough or “feigning” illness could transform one into a perceived enemy of the regime, and the regime resolutely hunted its enemies.

Reasons for torture and execution included expressing doubts about the government; having a prerevolutionary past as an intellectual, professional, teacher, or servant of the old regime; or growing one’s own food. The Khmer Rouge also gorged on its own with frequent brutal purges within the Khmer Rouge ranks. Soldiers, fellow workers, even one’s own children were encouraged to report on one’s incorrect thoughts or actions. The Khmer Rouge did little to engage in re-education of those found to have erred. Interrogation involved torture meant to elicit confessions of wrong-doing, thus proving the party’s correctness in arresting the person; death came during torture or soon thereafter. Fewer than ten persons are known to have survived the regime’s most notorious torture camp, S-21 in Phnom Penh.

It was from the S-21/Tuol Sleng facility that victims were taken to Cambodia’s most well-known killing field site at Choeung Ek, nine miles outside the capital, where victims were killed by blunt-force trauma (a rifle butt or farm implement to the base of the head), stabbing/hacking, or shooting. In the early twenty-first century, at Choeung Ek, a stupa (Buddhist shrine) of human skulls and a map of the country made of skulls and other bones remind visitors of the horror once meted out there. Almost 9,000 sets of remains have been excavated from the Choeung Ek grounds. Many more bodies remain buried, though, as tens of graves at the site have been left undisturbed.

The regime crumbled in 1979 due to a Vietnamese invasion, after which S-21 was transformed into the Tuol Sleng Museum of Genocide. Following a United Nations (UN)—brokered peace plan in 1991 and elections in 1993, the Khmer Rouge was gradually sidelined. In conjunction with the United Nations, Cambodia agreed in 2003 to set up a mixed Cambodian/international tribunal to bring remaining top Khmer Rouge leaders to justice for their crimes while in power.

Kimathi, Dedan

1920–1957

Dedan Kimathi (also known as Kimathi wa Waciuri) was an important member of Kenya’s militant nationalist group, the Mau Mau. He became notorious as the elusive “general.” Born in 1920 in the village of Thergengne in the Tetu Division of the Central Nyeri district in Kenya, Kimathi began his formal education at the age of fifteen when he enrolled at the local elementary school, Karunaini. He funded his education by collecting seeds for the forestry department. He later entered the Tumutumu CMS School, but could not complete his secondary education due to a lack of funds. In 1941 Kimathi enlisted in the army to help prosecute World War II (1939–1945), but he was discharged three years later for misconduct. In 1946 he became a member of the Kenyan African Union (KAU), a political organization established to fight British colonialism. In 1949 he returned to teach briefly at his former elementary school, but quit within two years.

In 1950 Kimathi embraced radical politics when he subscribed to the oath of the Mau Mau, the group demanding freedom and the return of Kenyan land from the British. Kimathi became one of the most prominent of the three dominant leaders of Mau Mau’s Land and Freedom Armies, with oversight functions for the Aberdare forest. In 1952 he was elected the local branch secretary of the KAU in the Ol’ Kalou and Thomson’s Falls area. He was arrested the same year when he was implicated in a murder, but he escaped from police detention with the help of a sympathizer. The following year he created the Kenya Defense Council to coordinate guerrilla activities, and moved to the Nyandarua forest, which served as the operational base of his army. In 1952 he was elected the local branch secretary of the KAU in the Ol’ Kalou and Thomson’s Falls area. He was arrested the same year when he was implicated in a murder, but he escaped from police detention with the help of a sympathizer. The following year he created the Kenya Defense Council to coordinate guerrilla activities, and moved to the Nyandarua forest, which served as the operational base of his army. Besides the armed struggle, he toured the forest and towns attempting to inspire people to join his group. Kimathi soon developed skills as a strategist and became an accomplished master of disguises. In addition, he became a skillful writer, penning letters to the colonial authorities and to friendly and unfriendly chiefs, as well as articles that were published in newspapers. Due to the activities of the Mau Mau, the colonial regime was forced to declare a state of emergency in 1952.

In 1956 Kimathi was captured with Wambui, his “forest wife,” and sentenced to death. He was hanged on February 18, 1957, at Nairobi Prison and was buried in a mass grave. Despite attempts by British propagandists to label him a dangerous and elusive terrorist, Kimathi became a folk hero among the people of Kenya. After independence, several towns in Kenya named buildings or streets after him. A statue was also dedicated to him in Nairobi in December 2006. Kimathi’s life has inspired several literary and historical works, including *The Trial of Dedan Kimathi* (1976) by Ngugi wa Thiong’o and Micere Mugo, and *L’inafferrabile Mau Mau* (The Elusive Mau Mau, 1957), a novel by Ottavio Sestero. Kimathi also lives on in the history, legends, and music of ordinary Kenyans.

Kindleberger, Charles Poor

1910–1993

Charles Kindleberger’s career unfolded in three distinct phases: public service; university teaching; and postretirement scholarship. A native New Yorker, he entered Columbia University’s doctoral program in 1932 near the bottom of the Great Depression. His first employers were the U.S. Treasury and the Federal Reserve. As World War II approached, he moved to the Bank for International Settlements in Switzerland, returning to Washington in 1940. After Pearl Harbor, he served with the Office of Strategic Services (OSS) and the U.S. Army in Europe. An unpretentious man of Kantian moral standards, he was overjoyed to have played an important role at the State Department in establishing the Marshall Plan for
European Recovery. Kindleberger moved to the Massachusetts Institute of Technology in 1948, where he remained until he retired in 1976. In response to the warmth, wit, and wisdom he showered on students and colleagues alike, he was universally known as “Charlie” or “cpk.”

Kindleberger enjoyed contrasting his expertise in old-fashioned “literary economics” with the more-circumscribed “technical economics” practiced by his colleagues and graduate students. The belief that he could help government policymakers avoid a repeat of signal economic disasters served as the cornerstone of his sixty-year professional life.

Unlike most of his contemporaries, Kindleberger made his mark through books, words, and index cards rather than with articles, equations, and datasets. His curiosity, energy, and vision overspread not only the page limits enforced by journal editors, but the narrow taxonomy of problem areas and research paradigms recognized in modern economics.

His teaching and research in international economics embraced the idea that nations, exchange-rate regimes, and technologies had ineluctable life cycles. His efforts to document these cycles spilled increasingly into what he teasingly renamed “historical economics.”

The transition became clear in 1964 with the publication of Economic Growth in France and Britain: 1851–1950, but reached full flower only after his retirement. Kindleberger saw himself not as doing history, but as using “historical episodes to test economic models for their generality” (Kindleberger 1990, p. 3). His research method was to read everything he could find on a subject and then to turn what he had learned into a coherent explanation of things. The eclectic syntheticizations this method produced challenged the methodological foundations of both financial history (The World in Depression, 1929–1939, 1973) and mainstream finance (Manias, Panics, and Crashes: A History of Financial Crises, 1978).

Both books portray financial institutions and markets as so volatile and prone to crisis that they must be stabilized by government. The World in Depression, 1929–1939 developed the thesis that the instability of national economies between the wars was a global problem that was enabled to spread by the absence of a dominant nation-state (a “hegemon”) willing and able to act as an international lender of last resort. Manias, Panics, and Crashes sought to refute the widely held hypothesis that participants in financial markets process information rationally.

These studies stand out from Kindleberger’s other twenty-eight books in the size, heat, and durability of the controversies they produced. On one side of the debate, opponents in political science and finance dispute the empirical applicability of his models of irrational actors and breakdown-prone markets and institutions. Many of these critics see government action as more likely to spawn or exacerbate institutional and market failures than to prevent or mitigate them. On the other side, Kindleberger attracted many followers and is remembered as a founding father of the fields of hegemonic stability and behavioral finance. He spent his last years energetically preparing new editions that answered specific critics and applied his models to additional episodes.

**KING, MARTIN LUTHER, JR.**

**1929–1968**

Martin Luther King Jr. was a Baptist minister and iconic leader of the U.S. civil rights movement. Famous for advocating nonviolent resistance to racial oppression, he led numerous demonstrations, boycotts, and voter registration drives from the mid-1950s until his death by assassination in 1968. King was fueled by a strong religious faith, believing that Christian love could function as a powerful agent for social change.

Both his maternal grandfather, A. D. Williams, and his father, Martin Luther King, were Baptist ministers and leaders of Ebenezer Baptist Church in Atlanta, Georgia. King carried on the family tradition, becoming an ordained Baptist minister at the age of eighteen. After completing a sociology degree from Morehouse College, a historically black institution in Atlanta, King attended
raced nonviolently to white supremacy. In 1963 the SCLC joined
a student at the New England Conservatory of Music. The marriage produced four children. In 1954 the couple
moved to Montgomery, Alabama, where King became pastor of the Dexter Street Baptist Church.

EMERGENCE AS A CIVIL RIGHTS
LEADER
Shortly after moving to Montgomery, King was cat-apulted into the growing civil rights movement. On December 1, 1955, local civil rights activist Rosa Parks (1913–2005) was arrested after she refused to give up her seat to a white passenger on a segregated city bus. The local black community organized a bus boycott to protest Parks’s arrest and elected King as leader of the Montgomery Improvement Association, an organization created to support the boycott. Under King’s leadership, the black community responded nonviolently to white intimidation and violence and sustained the boycott for over a year. In 1956 the Supreme Court ruled segregated seating on buses unconstitutional. King chronicled his involvement in the boycott in his powerful 1958 memoir Stride toward Freedom.

After the success in Montgomery, King and a group of black ministers formed the Southern Christian Leadership Conference (SCLC) in 1957. King was elected leader of this new organization, which was designed to support various civil rights activities.

The SCLC was not the only civil rights organization operating in the United States at this time, but King and his followers were key players in many of the most memorable showdowns between civil rights activists and the forces of white supremacy. In 1963 the SCLC joined Reverend Fred Shuttlesworth in a campaign to end segregation in Birmingham, Alabama. Defying a court injunction forbidding protest activities, King was arrested on April 12, 1963. While in prison he penned his famous “Letter from Birmingham Jail,” eloquently defending civil disobedience and urging religious leaders to enlist in the struggle for civil rights.

Local Birmingham officials, shamed by national media coverage of police attacking unarmed protestors with fire hoses and police dogs, reluctantly agreed to many of the activists’ demands. However, white resistance did not immediately abate. On September 15, 1963, in a particularly gruesome display of violence, the Ku Klux Klan bombed the Sixteenth Street Baptist Church, killing four young African American girls.

The SCLC and other civil rights advocates met similarly mixed results elsewhere, winning concessions but drawing violent reprisals from white supremacists. The SCLC was involved in many demonstrations including campaigns in Albany, Georgia, and Selma, Alabama. The federal government eventually responded to the problem of racial inequality by passing important civil rights legislation. The Civil Rights Act of 1964 outlawed discrimination in public facilities and in employment, and the Voting Rights Act of 1965 effectively put an end to disenfranchisement on the basis of race.

INTERNATIONAL FAME
King quickly became the most visible face of the civil rights struggle, capturing media attention wherever he went. On several occasions he met with President John F. Kennedy and later with President Lyndon B. Johnson. In 1963 he was named Time magazine’s “man of the year,” and in 1964 he was awarded the Nobel Peace Prize. During the 1963 March on Washington for Jobs and Freedom, he delivered his sonorous “I Have a Dream” speech, one of the most memorable examples of American oratory in the twentieth century.

Due in part to growing resentment over King’s fame, tensions developed between the SCLC and other civil rights organizations. The National Association for the Advancement of Colored People (NAACP) focused on fighting white supremacy through litigation rather than through the direct-action campaigns favored by the SCLC, causing tactical disagreements between members of the respective groups. Leaders of all the major civil rights organizations vied with one another and with King for media coverage and for opportunities to shape the direction of the movement. Roy Wilkins, executive secretary of the NAACP, was no exception. After NAACP field secretary Medgar Evers’s death by assassination on June 11, 1963, Wilkins became resentful of King’s efforts to raise funds in honor of the slain man, demanding instead that memorial contributions be sent exclusively to the NAACP. Despite these pressures, King remained an
ardent supporter of Wilkins and of the venerable civil rights organization he represented.

Similarly, many members of the Student Nonviolent Coordinating Committee (SNCC) offered powerful critiques of King. Some resented the media’s depiction of King as the predominant leader of the movement, referring to King in jest as “De Lawd.” Weary of being jailed and beaten, many young activists grew increasingly skeptical of King’s dedication to nonviolent resistance. Others began to embrace black nationalism rather than King’s integrationist vision for the United States. King remained receptive to criticism, and these profound disagreements did not stand in the way of warm, personal relationships between King and many SNCC members, including Stokely Carmichael (1941–1998), the radical black nationalist who was elected to the chairmanship of SNCC in 1966.

Malcolm X (1925–1965), the charismatic minister of the Nation of Islam and later, founder of the Organization of Afro-American Unity, was critical of nonviolent resistance, a tactic he regarded as cowardly. Malcolm was particularly outspoken in his criticisms of King, labeling him a “traitor to the Negro people.” King was stung by Malcolm’s condemnation, but the pair shared a well-publicized handshake on Capitol Hill on March 26, 1964. Although he continued to repudiate nonviolent resistance, Malcolm later sought ways to cooperate with King and other civil rights leaders. However, King rebuffed Malcolm’s efforts, certain that his fiery rhetoric and failure to embrace nonviolence would “reap nothing but grief.”

King was also a prominent target of the FBI director, J. Edgar Hoover (1895–1972). Hoover used wiretaps, spread false rumors, and planted infiltrators in an attempt to disrupt the movement and to tarnish the reputation of King and other leaders.

CHANGING DIRECTIONS
Throughout his life, King remained committed to the principal of nonviolent resistance, but his thinking did not become static. He listened thoughtfully to criticism and responded to the changing times. In 1965 he expanded the scope of his activism by speaking out against the Vietnam War. Increasingly, King began to focus on class issues, seeking ways to improve the lives of the underprivileged, regardless of race. In 1967 the SCLC began planning a Poor People’s Campaign designed to protest economic inequality through nonviolent direct action.

In 1968 King’s struggle for economic justice brought him to Memphis, Tennessee, to support striking sanitation workers. While there he gave what was to be his final address, “I’ve Been to the Mountaintop.” The recipient of frequent death threats, King long knew that his civil rights activism might cost him his life. That night he prophetically told his audience, “I might not get there with you … [but] we, as a people, will get to the Promised Land.” The next day, April 4, 1968, while standing on the balcony outside his hotel room, King was shot and killed by a sniper.

White supremacist James Earl Ray (1928–1998) was arrested for King’s murder. In order to avoid the death penalty, Ray made a plea bargain and confessed to the killing. However, Ray almost immediately recanted his confession, claiming that he was framed. In 1997 Ray convinced King’s son Dexter Scott King of his innocence, but Tennessee authorities refused to grant Ray, who died in prison in 1998, a new trial. King’s death has been the subject of many conspiracy theories, some involving the federal government in the plot to kill King.

Today King’s vision of interracial harmony has gained widespread acceptance among many Americans. However, his radical critique of economic inequality in the United States is less widely remembered. In 1983 Congress voted to establish a national holiday in his honor, enshrining King among the nation’s pantheon of heroes.

KINSEY, ALFRED
1894–1965
No figure in twentieth-century American sexuality is more influential, controversial, or misunderstood than

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION 269
Alfred Charles Kinsey. Kinsey was born on June 23, 1894, in Hoboken, New Jersey, a product of working-class Protestant culture. Throughout his life, Kinsey struggled with the contradictions of a profoundly moralistic attitude toward sexuality and faith, a love of nature and the Boy Scouts, and a zealous commitment to purge sexual education of its religiosity and moralism. Following a doctor of science degree from Harvard University (1919), Kinsey became a highly respected entomologist and naturalist, with an unshakable belief in science and a fascination with sex. His research was undertaken primarily at Indiana University beginning in 1920, where he eventually founded the Kinsey Institute (1946) and conducted the largest survey study of American sexuality, unsurpassed until the 1990s.

Kinsey’s work represented a scientific reaction to Sigmund Freud’s (1856–1939) popular developmental sexuality and the sexual “psychopath” laws that sprang from its medical model. Kinsey famously created a population-based questionnaire emphasizing the diversity of sexuality and the collection of representative numbers of individual interviews to understand sexual behavior across the course of life. Even homosexuality was, for Kinsey, a variation of the norm, and unlike Freud, Kinsey believed that it was better to express, rather than sublimate, these desires. Culture was largely an impediment to sexuality in his model, however, since he believed that culture and religion undermined sexual desire and pleasure, resulting in “unnecessary” sexual taboos.

Between the late 1930s and 1950s, Kinsey and colleagues collected more than 5,300 male sexual histories and 5,940 female histories, many actually conducted by Kinsey, subsequently published in two books: Sexual Behavior in the Human Male (1948) and Sexual Behavior in the Human Female (1953). Demonstrating that Americans’ beliefs were at odds with “reality,” Kinsey showed that masturbation, homosexuality, and premarital and extramarital sexual relations for men and women were far more common than previously believed. The famous “Kinsey scale” of heterosexual to homosexual, based upon seven kinds of preference, countered the conventions of male/female, heterosexual/homosexual binariness. The methodology was criticized for its white male bias, behavioralism, lack of African American sample, and overrepresentation of homosexuals. Although Kinsey sometimes interviewed the same person at two different times, he always used only the most recent interview score, which was aggregated into the general sample, thus mitigating against the sense of dynamic change across the life course of individuals (Herdt 1990).

Politically attacked from its inception, Kinsey’s research facilitated social progress in attitudes and laws regarding American sexuality, particularly on issues surrounding the frequency of female sexual pleasure and masturbation, the normalization of homosexuality, and sexual expression outside of marriage. Such cultural changes, of course, represented challenges to gender and familial stereotypes and cold war ideologies. Historians have argued that Kinsey’s empirical data—such as, for example, the finding that 37 percent of all American males had had some homosexual experience—was significant in changing sexual attitudes, perhaps laying the groundwork for second-wave feminism, the sexual revolution, and the gay and lesbian social movement. By compelling a different understanding of the world in which they were growing up, individuals who came of age under the influence of the Kinsey reports in the media and popular culture of the late 1950s and early 1960s greeted sexuality through the lens of changing norms about masturbation, female sexuality, and homosexuality. The absolute influence of taboos and laws was to some extent mediated by a growing idea of cultural relativism and social constructionism in universities. Armed with new knowledge and data that laid the foundation for social advocacy in society and the university, second-wave feminism and the gay and lesbian movement began the push toward greater tolerance for new gender roles and sexual diversity in America. In subsequent decades, the roots of these changes in Kinsey’s works were sometimes eclipsed, but a rash of new biographies and filmic studies suggests a renewed appreciation for the pivotal role of this seminal thinker in American sexuality.

Kinship

Kinship refers to relationships among individuals and groups that are based on descent or marriage. The study of kinship covers how different cultures conceptualize these relationships, the linguistic terms by which they distinguish and classify kin, marriage rules and practices, and the social, political, economic, religious, and symbolic uses that human societies make of kinship. Kinship is a human universal, found in all societies, although the cross-cultural variation in all these aspects of kinship is significant.

Anthropologists use a particular set of symbols to represent kinship relations, see Figure 1. These symbols are used to construct kinship diagrams for many different purposes. For example, they can be used to represent an individual’s genealogy as in Figure 2, which shows a male (called “ego” and shaded in the diagram) in relation to an array of relatives. This diagram also shows that ego’s four grandparents are deceased and that while many of ego’s relatives are married, his mother’s brother is divorced and his mother’s brother’s son is unmarried but has a sexual relationship with a partner.

The diagram labels ego’s kin with English terms that follow the Eskimo terminology system (named after the Inuit, who were once called Eskimos). Other terminology systems classify kin differently. For example, in the Hawaiian system, ego calls all female kin of his parent’s generation (mother, mother’s sister, and father’s sister) by the same term he or she uses for mother. Worldwide, there are only a few major types of kinship terminology systems.

As with kinship terminology systems, societies vary in how they trace descent and how they use it to form important groups. Some societies follow unilinear descent, meaning that they trace membership in descent groups through one gender only. Unilinear descent may be either patrilineal (tracing descent only through males) or matrilineal (tracing descent only through females). In patrilinear descent, both male and female children inherit...
affiliation with their father’s descent group, but only males pass on membership to their children. Chinese societies show examples of patrilineal descent. In the matrilineal case, male and female children are members of their mother’s descent group, but only females pass on this membership to their children. The Navajo Native Americans are an example of a matrilineal group. Unilineal societies trace descent through one gender only, but in virtually all societies individuals trace many other ties of kinship bilaterally, or through both parents.

Other societies trace descent cognitively, or through both males and females. All descendants of a founding ancestor may be members of the descent group. An example is the Kwaio of the Solomon Islands, where cognatic descent groups control territory and their members have rights to use this land. Most people of Europe and North America perceive descent cognitively but do not use this principle of descent to form significant groups.

Worldwide, patrilineal descent is the most common, covering an estimated 44 percent of world cultures. Societies tracing descent through both genders account for another 36 percent, whereas matrilineal descent covers about 15 percent of world cultures. Another rare descent type accounts for the final 5 percent.

Many societies with unilineal or cognatic descent use these descent principles to form important groups such as lineages and clans. Lineages are kin groupings in which members are cognizant of the paths through which they trace common descent. Clans are kin groups in which the exact routes by which people trace common descent are not known or considered: Individuals simply know their clan affiliations by inheriting a clan name from a parent. Some societies have both clans and lineages, in which case the lineages are subdivisions of the clans. The founding ancestors of clans are often considered to be mythological animals, plants, or special objects. Many clans have origin myths about how they were created from such mythological forces.

In many societies descent reckoning thus links individuals and groups together into larger kinship units in such a way that descent is a fundamental framework for the social and political organization of a people. In some societies descent groups are extremely important and powerful. They can be large corporations, owning property and other resources in common and transmitting rights to such property over the generations. Often descent groups are interwoven with religion, where, for example, members worship their ancestors in common.

One of the ways in which descent groups are important in the lives of individuals is that descent group membership specifies whom one may or may not marry. Very often descent groups are exogamous, that is, marriage is forbidden within them. In these cases, descent groups may arrange marriages with outside groups as a means of forging important social and political alliances with them. In other cases, descent group endogamy, or marriage within the group, is permitted or encouraged; for example, a man in a patrilineal system may be allowed or encouraged to marry his father’s brother’s daughter (or a father’s father’s brother’s son’s daughter). One consequence of descent group endogamy is that the wealth that both brides and grooms may inherit can be kept within the descent group.

Like notions of descent, the institution of marriage is found in all human cultures. Marriage may either be monogamous (two people, usually a man and a woman, are united in marriage), polygynous (a man is married to more than one woman at the same time), or polyandrous (a woman is married to more than one man at the same time). Monogamous marriages are the most common worldwide. Many societies permit polygyny, but in these, polygynous unions may account for only a fraction of all marriages. Polyandry is rare, but is found among some Tibetan populations and a few other groups.

Along with relationships of descent and marriage, anthropologists have studied how societies construct so-called “fictive” kinship, that is, kin-like relationships locally understood to be apart from standard kinship. Examples include adopted children, ritual siblings such as “blood brothers,” and godparents. These kinds of relationships are found worldwide.

The study of family relationships is important in many social sciences, but kinship studies developed as a particularly significant specialty within the discipline of anthropology. Beginning in the late nineteenth century, the work of Lewis Henry Morgan (1818–1881) in the United States brought kinship into the fold of the discipline. Morgan focused on kinship terminology systems and interpreted them as reflecting earlier levels or stages of peoples’ cultural evolution. This evolutionary perspective of Morgan and others was discredited by later anthropologists, but ever since Morgan, kinship study has continued to reflect the currents of the broader theoretical perspectives within anthropology.

By the 1970s anthropology had accumulated a considerable body of kinship data worldwide. But by this time also, some anthropologists contended that anthropological concepts of kinship had grown too rigid, that they did not quite fit with the way local peoples themselves were conceptualizing their own kinship. In this context, David Schneider in the United States and Rodney Needham in England charged that anthropological kinship was seriously flawed. Schneider in particular pointed out that anthropological concepts of kinship were rooted in notions of biological procreation, reflecting “kinship” as understood in the particular cultural framework of the
Western world. However, other cultures often construct “kinship” relationships on other bases, such as common residence or food sharing. In other words, the anthropological concept of kinship had been an ethnocentric imposition of Western cultural constructs on other cultures.

With this critique, kinship in anthropology suffered a twenty-year decline, although it was kept alive within feminist anthropology, where it was studied in relation to gender. By this time a shift in kinship studies was evident. Over the first half of the twentieth century anthropologists studied kinship primarily as a key to peoples’ social, political, and economic structures, often drawing comparisons among cultures. Through the 1980s, by contrast, kinship studies were conducted from within each culture separately, in terms of purely local categories and cultural meanings.

Kinship not only survived in anthropology, but, beginning in the 1990s, it revived. Influencing this revival was Janet Carsten, who sought to broaden the concept of kinship to make it cross-culturally valid. The work of Carsten and others also reflected another trend: the view of kinship as process. Their research demonstrated that in many societies kinship statuses or ties are not set once and for all by acts of birth, but rather emerge, strengthen, or fade through the process of human interactions, for example, the giving and receiving of food. Kinship studies of this period also incorporated the idea of kinship as choice. In the United States and Europe, for example, studies of gay or lesbian families, as well as studies of “blended” families consisting of stepparents and stepsiblings, have shown that meaningful kinship construction can be as much a matter of choice and commitment as biological connection.

In the opening decades of the twenty-first century the central question of kinship studies became not so much “How do kinship systems work?” but rather, “How do people work cultural constructions of kinship?” How do individual human actors confirm, challenge, or change these constructions? With this emphasis kinship studies focused on a wide variety of topics, including the impact on kinship constructions of the new reproductive technologies and new family forms, and the intersection of kinship with political struggles and transformations.

KINSHIP, EVOLUTIONARY THEORY OF

Altruistic behavior—“self-sacrificial behavior performed for the benefit of others” (Wilson 1975, p. 578)—has long been a paradox for evolutionary theorists, because natural selection favors traits that contribute to the reproductive success (“individual fitness”) of those who possess or perform them. Hence, altruism, which by definition contributes to the reproductive success of competitions at the expense of performers, ought not to evolve by natural selection. Yet it is widespread in nature. The sterile worker castes in bees, ants, and wasps provide prime examples (Wilson 1975). In 1964 William Hamilton, a graduate student at the University of London, saw that biological altruism can evolve, even though it reduces the individual reproductive success of the help’s donor, if it aids the donor’s genetic kin, some of whom inherit the helping allele from a common ancestor of the donor and recipient.

Consider $C$, the cost to a donor of a helping act, and $B$, the benefit of the act to a recipient. Hamilton’s statement can be expressed as $Br_1 > Cr_2$ where $r_1$ equals the probability that the recipient’s offspring has a copy of a helping allele inherited from a common ancestor of the donor and recipient, such as a parent or grandparent; and $r_2$ equals the probability that the donor’s own offspring would have a copy of the same helping allele inherited from a common ancestor, such as a parent or grandparent. These probabilities are called “genetic correlations” or “coefficients of relatedness” between individuals.

As an example, consider a donor who inherited a helping allele from his mother for giving up one offspring to help a half-sibling produce three additional offspring. This allele was inherited via the common parent of the half siblings, their mother. When an organism reproduces, only one of each pair of chromosomes is passed to its gamete (Mendel’s law of segregation), which unites with a gamete from another individual to produce the zygote.
Kissinger, Henry

that grows into an adult. Therefore, the probability that any particular allele at a locus on a chromosome in a parent is passed on to its offspring is 0.5. There are two gamete-producing reproductive events between the donor and any of his or her three additional half nieces or nephews produced because of the help: One produces the half-sibling that is being helped; the other produces each of the three offspring of the half-sibling who is being helped (the half-nieces and half-nephews of the donor) because of the help. Therefore, there is a $0.5 \times 0.5 = 0.25$ chance that any one of them inherits a copy of the helping allele possessed by the donor, their uncle or aunt. Putting these numbers into the above equation produces $3(0.25) > 1(0.50); 0.75 > 0.50$.

Hence, natural selection can favor the evolution of psychological mechanisms for producing helping behaviors directed to genetic relatives. Note that both sides of the equation refer to changes in the helper's reproductive success because of helping acts. The right side, $Cr_j$, indicates the direct reproductive cost to the donor through offspring not produced, whereas the left side, $Br_j$, indicates the indirect reproductive benefits to the donor through additional offspring—a genetic relative produced because of the help. This reasoning leads to replacing the concept of individual fitness with the concept of “inclusive fitness,” the reproductive success of an individual adjusted by the help it gives and receives from genetic relatives. Kin selection refers to natural selection acting via inclusive fitness rather than via individual fitness. Finally, note that those desiring an evolutionary explanation for “true altruism,” in which a donor receives no benefit for a helping act, will not find it in Hamilton's equation.

Hamilton's paper (1964) is one of the most important scientific papers of the twentieth century. First, it enables evolutionary explanations for a wide range of social interactions in organisms (Alcock 2005; Wilson 1975) and humans (Burnstein 2005; Buss 2004). Second, it shifted the focus in evolutionary thinking from the reproduction of individuals to the replication of genes. Albert Einstein gave us relativity theory when he imagined how the universe would look if he were riding on a beam of light; Hamilton gave us a new way of thinking about evolution when he imagined how natural selection would seem to work if he were riding on a gene as it crossed generations.

KISSINGER, HENRY

1923–

Born Heinz Alfred Kissinger on May 27, 1923 in Fürth, Germany, Kissinger and his family escaped Nazi persecution by immigrating to New York City in 1938. Kissinger joined the U.S. army during World War II, and later earned his BA, MA, and PhD in government at Harvard University. After joining the Harvard faculty, in 1955 and 1956 Kissinger served as director of a study group set up by the Council on Foreign Relations to analyze the influence of nuclear arms on international relations. Although he served as a consultant to the Democratic administrations of John F. Kennedy (1917–1963) and Lyndon B. Johnson (1908–1973), Kissinger tried but failed to secure a major, influential position under either Kennedy or Johnson. Generally indifferent to party affiliations, Kissinger also served as a foreign and defense policy adviser to Governor Nelson A. Rockefeller of New York (1908–1979), a liberal Republican with presidential ambitions during the 1960s.

Partly because Kissinger was identified with the Rockefeller faction of the Republican Party, President Richard M. Nixon appointed Kissinger national security adviser in 1969. Kissinger perceived the United States to be experiencing a period of relative decline in its international power during the 1970s. He believed that U.S. foreign policy needed to adapt to this relative decline by practicing “power politics,” or the politics of “realism,” by reducing its ideological hostility and distrust of the Soviet Union and mainland China and protecting U.S. interests through the creation and maintenance of a balance of power and spheres of influence among major world powers. Kissinger had studied and developed the ideas of “realism” in international relations since he was a student.
at Harvard. His application of “realism” in Nixon’s and Ford’s foreign and defense policies was evident in the gradual U.S. military withdrawal from Vietnam, the negotiation and signing of the Strategic Arms Limitation Treaty (SALT) with the Soviet Union in 1972, and Nixon’s diplomatic visit to Communist China in 1972. For their efforts in negotiating and securing a peace treaty to end the Vietnam War, Kissinger and Le Duc Tho, a North Vietnamese diplomat, received the Nobel Peace Prize in 1973.

Kissinger, however, found the practice of “power politics” to be more difficult in the Middle East. Oil-producing nations in the Middle East imposed an embargo on oil exports to the United States, and U.S.-Soviet relations were strained because of U.S. support of Israel during the Yom Kippur War of 1973. Nonetheless, Kissinger’s diplomacy helped to achieve cease-fire agreements between Israel and Egypt and Israel and Syria. During the 1976 presidential election, Kissinger’s “realism” was criticized by Democratic presidential nominee Jimmy Carter (b. 1924) for neglecting human rights and lacking a moral purpose.

After leaving the Ford administration in 1977, Kissinger headed an international consulting firm, lectured, wrote his memoirs, and occasionally advised Presidents Ronald W. Reagan (1911–2004) and George H. W. Bush (b. 1924) on foreign policy. In 1983 Seymour Hersh, an American journalist, published The Price of Power, in which he implicated Kissinger in several controversial decisions of Nixon’s foreign policy such as the 1970 invasion of Cambodia, the massive U.S. bombing of North Vietnam in 1972, and the 1973 overthrow of President Salvador Allende of Chile. During the 1990s more national security documents and other government sources pertaining to Kissinger’s roles as national security adviser and secretary of state were made available to researchers. Using some of these primary sources, Christopher Hitchens, a British journalist, published The Trial of Henry Kissinger (2001), denouncing Kissinger as a war criminal. In particular, Hitchens argued that Kissinger’s influence on U.S. foreign policy prolonged the Vietnam War, violated human rights and international law, and contributed to politically motivated mass murders in Chile, Cambodia, East Timor, and elsewhere.

Kissinger refused to publicly comment on Hitchens’s book. He continued to lecture, write, and manage his consulting firm, Kissinger and Associates. He briefly served as chairman of the 9/11 Commission in 2002, but resigned after Democrats claimed that there were conflicts of interest between his chairmanship and consulting firm.

**KLEIN, LAWRENCE**

1920–

Lawrence R. Klein was born in Omaha, Nebraska, in 1920, graduated from the University of California at Berkeley in 1942, and went on to receive in 1944 the first PhD awarded by a Department of Economics at MIT that was, like himself, at the very beginning of a long and eminence career. Klein’s first post was a three-year stint as research associate of the Cowles Commission at the University of Chicago; Cowles was then strongly oriented to econometrics, and was certainly an important influence on Klein’s early research interests. In 1949 he migrated to teaching and research posts at the University of Michigan. He was driven from Ann Arbor, and from the United States, by the McCarthy witch hunt, and went in 1954 to the Institute of Statistics at Oxford. In 1958 he became professor of economics at the University of Pennsylvania, then University Professor and Benjamin Franklin Professor, until his formal retirement in 1991.

Klein’s long and distinguished career led to an enormous list of articles, many books, thirty or more honorary
degrees, a series of visiting professorships, the presidency of the Econometric Society in 1960 and the American Economic Association in 1977, the John Bates Clark Medal of the American Economic Association in 1959, and the Alfred Nobel Memorial Prize in Economic Sciences in 1980. It is safe to say that what honors were available, he has had.

Beginning with the publication of *Economic Fluctuations in the United States, 1921–1941* (1950), Klein succeeded the Dutch economist Jan Tinbergen (1903–1994) as the preeminent macroeconometric model builder in the United States and the world. With a series of coauthors, he produced a larger and improved model of the United States in 1955 and a model of the United Kingdom in 1961, participated in the Brookings quarterly econometric model of the United States (1965, 1969, 1975), and was the guiding force in the Wharton model of the United States (1967, 1968). From its start in 1968, Klein led a large group of participants in Project LINK, a systematic effort to link together, through explicit trade and capital flows, as many national econometric models as could be mustered. In his eightieth year, Klein was actively engaged in the econometric modeling of the Chinese economy.

His first macroeconometric models were Keynesian in inspiration, drawing on *The Keynesian Revolution* (1947, based on his PhD thesis). They were primarily models of aggregate demand. Later versions began to add a supply side and a model of inflation. In view of later controversies in academic macroeconomics, it is useful to note that one of Klein's earliest articles (1946) was on “Macroeconomics and the Theory of Rational Behavior.” In those days, attention to “microfoundations” amounted to asking if this or that macro-equation could arise from the approximate aggregation of the behavior of rational agents. That still seems more sensible than the current tendency to a much more literal interpretation that leads to the casual acceptance of extreme assumptions for no better reason.

From the beginning, Klein was motivated by the possibility that empirical macrocmodes could be used to guide fiscal and monetary policy, and to estimate the effects of other policy measures. Sixty years later, the technique is still highly imperfect. But nothing better has been found in practice; and central banks, government agencies, and international agencies all over the world maintain and use econometric models that are direct descendants of Klein's lifework.

**KNESET, THE**

The Knesset is the unicameral parliament of the State of Israel, and as such it is the country's highest legislative body. There are 120 members of Knesset (MK), who are elected to four-year terms in office. In addition to passing legislation, the Knesset also appoints Israel’s president—a largely symbolic position—and the state comptroller. In addition, the Knesset has the authority to dissolve itself by simple majority, which would result in the holding of new elections and the formation of a new government. The Knesset meets in Jerusalem, the capital of Israel. When the State of Israel was initially established in May 1948, the Knesset sat in Tel Aviv. It moved to Jerusalem in December 1949 and has remained there ever since.
